The code that implements OpenImageIO is licensed under the Apache 2.0 license for all new code contributed after July 1, 2023, and any code from prior to that date which has been relicensed under Apache-2.0 by their owners. Code dating from prior to July 1, 2023 that has not been relicensed by their owners is licensed under the BSD 3-clause (also sometimes known as “new BSD” or “modified BSD”) license.

Apache License

Version 2.0, January 2004

<http://www.apache.org/licenses/>

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

“License” shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

“Licensor” shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

“Legal Entity” shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, “control” means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

“You” (or “Your”) shall mean an individual or Legal Entity exercising permissions granted by this License.

“Source” form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

“Object” form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

“Work” shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

“Derivative Works” shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

“Contribution” shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, “submitted” means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking

systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as “Not a Contribution.”

“Contributor” shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. **Grant of Copyright License.** Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.
3. **Grant of Patent License.** Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.
4. **Redistribution.** You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:
 - (a) You must give any other recipients of the Work or Derivative Works a copy of this License; and
 - (b) You must cause any modified files to carry prominent notices stating that You changed the files; and
 - (c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
 - (d) If the Work includes a “NOTICE” text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.
6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.
7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an “AS IS” BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.
8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.
9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work.

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets “[]” replaced with your own identifying information. (Don’t include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same “printed page” as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]

Licensed under the Apache License, Version 2.0 (the “License”); you may not use this file except in compliance with the License. You may obtain a copy of the License at

<http://www.apache.org/licenses/LICENSE-2.0>

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an “AS IS” BASIS, WITHOUT WARRANTIES OR CONDITIONS OF

ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

This manual and other text documentation about OpenImageIO are licensed under the Creative Commons Attribution 4.0 International License.

<http://creativecommons.org/licenses/by/4.0/>

OpenImageIO incorporates code from several other software packages with compatible licenses. Copies of their licenses are reproduced here: <https://github.com/AcademySoftwareFoundation/OpenImageIO/blob/main/THIRD-PARTY.md>

INTRODUCTION

Welcome to OpenImageIO!

I kinda like “Oy-e-oh” with a bit of a groaning Yiddish accent, as in
“OIIO, did you really write yet another file I/O library?”

Dan Wexler

1.1 Overview

OpenImageIO provides simple but powerful `ImageInput` and `ImageOutput` APIs that abstract the reading and writing of 2D image file formats. They don’t support every possible way of encoding images in memory, but for a reasonable and common set of desired functionality, they provide an exceptionally easy way for an application using the APIs support a wide — and extensible — selection of image formats without knowing the details of any of these formats.

Concrete instances of these APIs, each of which implements the ability to read and/or write a different image file format, are stored as plugins (i.e., dynamic libraries, DLL’s, or DSO’s) that are loaded at runtime. The OpenImageIO distribution contains such plugins for several popular formats. Any user may create conforming plugins that implement reading and writing capabilities for other image formats, and any application that uses OpenImageIO would be able to use those plugins.

The library also implements the helper class `ImageBuf`, which is a handy way to store and manipulate images in memory. `ImageBuf` itself uses `ImageInput` and `ImageOutput` for its file I/O, and therefore is also agnostic as to image file formats. A variety of functions in the `ImageBufAlgo` namespace are available to perform common image processing operations on `ImageBuf`’s.

The `ImageCache` class transparently manages a cache so that it can access truly vast amounts of image data (thousands of image files totaling hundreds of GB to several TBs) very efficiently using only a tiny amount (tens of megabytes to a few GB at most) of runtime memory. Additionally, a `TextureSystem` class provides filtered MIP-map texture lookups, atop the nice caching behavior of `ImageCache`.

Finally, the OpenImageIO distribution contains several utility programs that operate on images, each of which is built atop this functionality, and therefore may read or write any image file type for which an appropriate plugin is found at runtime. Paramount among these utilities `oiiotool`, a command-line image processing engine, and `iv`, an image

viewing application. Additionally, there are programs for converting images among different formats, comparing image data between two images, and examining image metadata.

All of this is released as “open source” software using the very permissive “BSD 3-clause” license. So you should feel free to use any or all of OpenImageIO in your own software, whether it is private or public, open source or proprietary, free or commercial. You may also modify it on your own. You are encouraged to contribute to the continued development of OpenImageIO and to share any improvements that you make on your own, though you are by no means required to do so.

1.2 Simplifying Assumptions

OpenImageIO is not the only image library in the world. Certainly there are many fine libraries that implement a single image format (including the excellent `libtiff`, `libjpeg`, and `OpenEXR` that OpenImageIO itself relies on). Many libraries attempt to present a uniform API for reading and writing multiple image file formats. Most of these support a fixed set of image formats, though a few of these also attempt to provide an extensible set by using the plugin approach.

But in our experience, these libraries are all flawed in one or more ways: (1) They either support only a few formats, or many formats but with the majority of them somehow incomplete or incorrect. (2) Their APIs are not sufficiently expressive as to handle all the image features we need (such as tiled images, which is critical for our texture library). (3) Their APIs are *too complete*, trying to handle every possible permutation of image format features, and as a result are horribly complicated.

The third sin is the most severe, and is almost always the main problem at the end of the day. Even among the many open source image libraries that rely on extensible plugins, we have not found one that is both sufficiently flexible and has APIs anywhere near as simple to understand and use as those of OpenImageIO.

Good design is usually a matter of deciding what *not* to do, and OpenImageIO is no exception. We achieve power and elegance only by making simplifying assumptions. Among them:

- OpenImageIO only deals with ordinary 2D images, and to a limited extent 3D volumes, and image files that contain multiple (but finite) independent images within them. OpenImageIO’s support of “movie” files is limited to viewing them as a sequence of separate frames within the file, but not as movies per se (for example, no support for dealing with audio or synchronization).
- Pixel data are presented as 8- 16- or 32-bit int (signed or unsigned), 16- 32- or 64-bit float. NOTHING ELSE. No < 8 bit images, or pixel value boundaries that aren’t byte boundaries. Files with < 8 will appear to the client application as 8-bit unsigned grayscale images.
- Only fully elaborated, non-compressed data are accepted and returned by the API. Compression or special encodings are handled entirely within an OpenImageIO plugin.
- Color space is by default converted to grayscale or RGB. Non-spectral color models, such as XYZ, CMYK, or YUV, are converted to RGB upon reading. (There is a way to override this and ask for raw pixel values.)
- All color channels can be treated (by apps or readers/writers) as having the same data format (though there is a way to deal with per-channel formats for apps and readers/writers that truly need it).
- All image channels in a subimage are sampled at the same resolution. For file formats that allow some channels to be subsampled, they will be automatically up-sampled to the highest resolution channel in the subimage.
- Color information is always in the order R, G, B, and the alpha channel, if any, always follows RGB, and Z channel (if any) always follows alpha. So if a file actually stores ABGR, the plugin is expected to rearrange it as RGBA.

It’s important to remember that these restrictions apply to data passed through the APIs, not to the files themselves. It’s perfectly fine to have an OpenImageIO plugin that supports YUV data, or 4 bits per channel, or any other exotic feature. You could even write a movie-reading ImageInput (despite OpenImageIO’s claims of not supporting movies)

and make it look to the client like it's just a series of images within the file. It's just that all the nonconforming details are handled entirely within the OpenImageIO plugin and are not exposed through the main OpenImageIO APIs.

1.3 Historical Origins

OpenImageIO is the evolution of concepts and tools I've been working on for two decades.

In the 1980's, every program I wrote that output images would have a simple, custom format and viewer. I soon graduated to using a standard image file format (TIFF) with my own library implementation. Then I switched to Sam Leffler's stable and complete `libtiff`.

In the mid-to-late-1990's, I worked at Pixar as one of the main implementors of PhotoRealistic RenderMan, which had *display drivers* that consisted of an API for opening files and outputting pixels, and a set of DSO/DLL plugins that each implement image output for each of a dozen or so different file format. The plugins all responded to the same API, so the renderer itself did not need to know how to the details of the image file formats, and users could (in theory, but rarely in practice) extend the set of output image formats the renderer could use by writing their own plugins.

This was the seed of a good idea, but PRMan's display driver plugin API was abstruse and hard to use. So when I started Exluna in 2000, Matt Pharr, Craig Kolb, and I designed a new API for image output for our own renderer, Entropy. This API, called "ExDisplay," was C++, and much simpler, clearer, and easier to use than PRMan's display drivers.

NVIDIA's Gelato (circa 2002), whose early work was done by myself, Dan Wexler, Jonathan Rice, and Eric Enderton, had an API called "ImageIO." ImageIO was *much* more powerful and descriptive than ExDisplay, and had an API for *reading* as well as writing images. Gelato was not only "format agnostic" for its image output, but also for its image input (textures, image viewer, and other image utilities). We released the API specification and headers (though not the library implementation) using the BSD open source license, firmly repudiating any notion that the API should be specific to NVIDIA or Gelato.

For Gelato 3.0 (circa 2007), we refined ImageIO again (by this time, Philip Nemec was also a major influence, in addition to Dan, Eric, and myself¹). This revision was not a major overhaul but more of a fine tuning. Our ideas were clearly approaching stability. But, alas, the Gelato project was canceled before Gelato 3.0 was released, and despite our prodding, NVIDIA executives would not open source the full ImageIO code and related tools.

After I left NVIDIA, I was determined to recreate this work once again – and ONLY once more – and release it as open source from the start. Thus, OpenImageIO was born. I started with the existing Gelato ImageIO specification and headers (which were BSD licensed all along), and made further refinements since I had to rewrite the entire implementation from scratch anyway. I think the additional changes are all improvements.

Over the years and with the help of dozens of open source contributors, OpenImageIO has expanded beyond the original simple image format input/output to encompass a wide range of image-related functionality. It has grown into a foundational technology in many products and tools, particularly for the production of animation and visual effects for motion pictures (but also many other uses and fields). This is the software you have in your hands today.

¹ Gelato as a whole had many other contributors; those I've named here are the ones I recall contributing to the design or implementation of the ImageIO APIs.

1.4 Acknowledgments

OpenImageIO incorporates, depends upon, or dynamically links against several other open source packages, detailed below. These other packages are all distributed under licenses that allow them to be used by OpenImageIO. Where not specifically noted, they are all using the same BSD license that OpenImageIO uses. Any omissions or inaccuracies in this list are inadvertent and will be fixed if pointed out. The full original licenses can be found in the relevant parts of the source code.

OpenImageIO incorporates, distributes, or contains derived works of:

- The SHA-1 implementation we use is public domain by Dominik Reichl <http://www.dominik-reichl.de/>
- PugiXML © 2006-2009 by Arseny Kapoulkine (based on work © 2003 Kristen Wegner), MIT license. <http://pugixml.org/>

IMAGE I/O API HELPER CLASSES

2.1 Data Type Descriptions: TypeDesc

There are two kinds of data that are important to OpenImageIO:

- *Internal data* is in the memory of the computer, used by an application program.
- *Native file data* is what is stored in an image file itself (i.e., on the “other side” of the abstraction layer that OpenImageIO provides).

Both internal and file data is stored in a particular *data format* that describes the numerical encoding of the values. OpenImageIO understands several types of data encodings, and there is a special class, `TypeDesc`, that allows their enumeration and is described in the header file `OpenImageIO/typdesc.h`. A `TypeDesc` describes a base data format type, aggregation into simple vector and matrix types, and an array length (if it's an array).

The remainder of this section describes the C++ API for `TypeDesc`. See Section [Python Bindings](#) for the corresponding Python bindings.

struct **TypeDesc**

A *TypeDesc* describes simple data types.

It frequently comes up (in my experience, with renderers and image handling programs) that you want a way to describe data that is passed through APIs through blind pointers. These are some simple classes that provide a simple type descriptor system. This is not meant to be comprehensive; for example, there is no provision for structs, unions, pointers, const, or ‘nested’ type definitions. Just simple integer and floating point, *common* aggregates such as 3-points, and reasonably-lengthed arrays thereof.

Public Types

enum **BASETYPE**

BASETYPE is a simple enum describing the base data types that correspond (mostly) to the C/C++ built-in types.

Values:

enumerator **UNKNOWN**

unknown type

enumerator **NONE**

void/no type

enumerator **UINT8**

8-bit unsigned int values ranging from 0..255, (C/C++ unsigned char).

enumerator **UCHAR**

enumerator **INT8**

8-bit int values ranging from -128..127, (C/C++ char).

enumerator **CHAR**

enumerator **UINT16**

16-bit int values ranging from 0..65535, (C/C++ unsigned short).

enumerator **USHORT**

enumerator **INT16**

16-bit int values ranging from -32768..32767, (C/C++ short).

enumerator **SHORT**

enumerator **UINT32**

32-bit unsigned int values (C/C++ unsigned int).

enumerator **UINT**

enumerator **INT32**

signed 32-bit int values (C/C++ int).

enumerator **INT**

enumerator **UINT64**

64-bit unsigned int values (C/C++ unsigned long long on most architectures).

enumerator **ULONGLONG**

enumerator **INT64**

signed 64-bit int values (C/C++ long long on most architectures).

enumerator **LONGLONG**

enumerator **HALF**

16-bit IEEE floating point values (OpenEXR half).

enumerator **FLOAT**

32-bit IEEE floating point values, (C/C++ `float`).

enumerator **DOUBLE**

64-bit IEEE floating point values, (C/C++ `double`).

enumerator **STRING**

Character string.

enumerator **PTR**

A pointer value.

enumerator **USTRINGHASH**

The hash of a ustring.

enumerator **LASTBASE**

enum **AGGREGATE**

AGGREGATE describes whether our *TypeDesc* is a simple scalar of one of the BASETYPE's, or one of several simple aggregates.

Note that aggregates and arrays are different. A `TypeDesc(FLOAT, 3)` is an array of three floats, a `TypeDesc(FLOAT, VEC3)` is a single 3-component vector comprised of floats, and `TypeDesc(FLOAT, 3, VEC3)` is an array of 3 vectors, each of which is comprised of 3 floats.

Values:

enumerator **SCALAR**

A single scalar value (such as a raw `int` or `float` in C). This is the default.

enumerator **VEC2**

2 values representing a 2D vector.

enumerator **VEC3**

3 values representing a 3D vector.

enumerator **VEC4**

4 values representing a 4D vector.

enumerator **MATRIX33**

9 values representing a 3x3 matrix.

enumerator **MATRIX44**

16 values representing a 4x4 matrix.

enum VECSEMANTICS

VECSEMANTICS gives hints about what the data represent (for example, if a spatial vector quantity should transform as a point, direction vector, or surface normal).

Values:

enumerator NOXFORM

No semantic hints.

enumerator NOSEMANTICS

No semantic hints.

enumerator COLOR

Color.

enumerator POINT

Point: a spatial location.

enumerator VECTOR

Vector: a spatial direction.

enumerator NORMAL

Normal: a surface normal.

enumerator TIMECODE

indicates an `int[2]` representing the standard 4-byte encoding of an SMPTE timecode.

enumerator KEYCODE

indicates an `int[7]` representing the standard 28-byte encoding of an SMPTE keycode.

enumerator RATIONAL

A VEC2 representing a rational number `val[0] / val[1]`

enumerator BOX

A VEC2[2] or VEC3[2] that represents a 2D or 3D bounds (min/max)

Public Functions

```
inline constexpr TypeDesc(BASETYPE btype = UNKNOWN, AGGREGATE agg = SCALAR,  
                           VECSEMANTICS semantics = NOSEMANTICS, int arraylen = 0) noexcept
```

Construct from a BASETYPE and optional aggregateness, semantics, and arrayness.

```
inline constexpr TypeDesc(BASETYPE btype, int arraylen) noexcept
```

Construct an array of a non-aggregate BASETYPE.

```
inline constexpr TypeDesc(BASETYPE btype, AGGREGATE agg, int arraylen) noexcept
```

Construct an array from BASETYPE, AGGREGATE, and array length, with unspecified (or moot) semantic hints.

TypeDesc(string_view tpestring)

Construct from a string (e.g., “float[3]”). If no valid type could be assembled, set base to UNKNOWN.

Examples:

```
TypeDesc("int") == TypeDesc(TypeDesc::INT)           // C++ int32_t
TypeDesc("float") == TypeDesc(TypeDesc::FLOAT)       // C++ float
TypeDesc("uint16") == TypeDesc(TypeDesc::UINT16)     // C++ uint16_t
TypeDesc("float[4]") == TypeDesc(TypeDesc::FLOAT, 4) // array
TypeDesc("point") == TypeDesc(TypeDesc::FLOAT,
                               TypeDesc::VEC3, TypeDesc::POINT)
```

constexpr **TypeDesc**(const *TypeDesc* &t) noexcept = default

Copy constructor.

const char ***c_str**() const

Return the name, for printing and whatnot. For example, “float”, “int[5]”, “normal”

inline constexpr size_t **numelements**() const noexcept

Return the number of elements: 1 if not an array, or the array length. Invalid to call this for arrays of undetermined size.

inline constexpr size_t **basevalues**() const noexcept

Return the number of basetype values: the aggregate count multiplied by the array length (or 1 if not an array). Invalid to call this for arrays of undetermined size.

inline constexpr bool **is_array**() const noexcept

Does this *TypeDesc* describe an array?

inline constexpr bool **is_undefined_array**() const noexcept

Does this *TypeDesc* describe an array, but whose length is not specified?

inline constexpr bool **is_sized_array**() const noexcept

Does this *TypeDesc* describe an array, whose length is specified?

inline size_t **size**() const noexcept

Return the size, in bytes, of this type.

inline constexpr *TypeDesc* **elementtype**() const noexcept

Return the type of one element, i.e., strip out the array-ness.

inline size_t **elementsizes**() const noexcept

Return the size, in bytes, of one element of this type (that is, ignoring whether it’s an array).

inline constexpr *TypeDesc* **scalartype**() const

Return just the underlying C scalar type, i.e., strip out the array-ness and the aggregateness.

size_t **basesize**() const noexcept

Return the base type size, i.e., stripped of both array-ness and aggregateness.

bool **is_floating_point**() const noexcept

True if it’s a floating-point type (versus a fundamentally integral type or something else like a string).

bool **is_signed**() const noexcept

True if it’s a signed type that allows for negative values.

inline constexpr bool **is_unknown**() const noexcept

Shortcut: is it UNKNOWN?

inline constexpr **operator bool**() const noexcept
if (typedesc) is the same as asking whether it's not UNKNOWN.

size_t **fromstring**(string_view tpestring)
Set *this to the type described in the string. Return the length of the part of the string that describes the type. If no valid type could be assembled, return 0 and do not modify *this.

inline constexpr bool **operator==(const *TypeDesc* &t)** const noexcept
Compare two *TypeDesc* values for equality.

inline constexpr bool **operator!=(const *TypeDesc* &t)** const noexcept
Compare two *TypeDesc* values for inequality.

inline constexpr bool **equivalent**(const *TypeDesc* &b) const noexcept
Member version of equivalent.

inline constexpr bool **is_vec2**(*BASETYPE* b = FLOAT) const noexcept
Is this a 2-vector aggregate (of the given type, float by default)?

inline constexpr bool **is_vec3**(*BASETYPE* b = FLOAT) const noexcept
Is this a 3-vector aggregate (of the given type, float by default)?

inline constexpr bool **is_vec4**(*BASETYPE* b = FLOAT) const noexcept
Is this a 4-vector aggregate (of the given type, float by default)?

inline constexpr bool **is_box2**(*BASETYPE* b = FLOAT) const noexcept
Is this an array of aggregates that represents a 2D bounding box?

inline constexpr bool **is_box3**(*BASETYPE* b = FLOAT) const noexcept
Is this an array of aggregates that represents a 3D bounding box?

inline void **unarray**(void) noexcept
Demote the type to a non-array

bool **operator<**(const *TypeDesc* &x) const noexcept
Test for lexicographic 'less', comes in handy for lots of STL containers and algorithms.

Public Members

unsigned char **basetype**
C data type at the heart of our type.

unsigned char **aggregate**
What kind of AGGREGATE is it?

unsigned char **vecsemantics**
Hint: What does the aggregate represent?

unsigned char **reserved**
Reserved for future expansion.

int **arraylen**
Array length, 0 = not array, -1 = unsized.

Public Static Functions

static *BASETYPE* **basetype_merge**(*TypeDesc* a, *TypeDesc* b)

Given base data types of a and b, return a basetype that is a best guess for one that can handle both without any loss of range or precision.

Friends

inline friend constexpr friend bool operator== (const *TypeDesc* &t, *BASETYPE* b) **noexcept**

Compare a *TypeDesc* to a basetype (it's the same if it has the same base type and is not an aggregate or an array).

inline friend constexpr friend bool operator!= (const *TypeDesc* &t, *BASETYPE* b) **noexcept**

Compare a *TypeDesc* to a basetype (it's the same if it has the same base type and is not an aggregate or an array).

inline friend constexpr friend bool equivalent (const *TypeDesc* &a, const *TypeDesc* &b) **noexcept**

TypeDesc's are equivalent if they are equal, or if their only inequality is differing vector semantics.

A number of static `constexpr TypeDesc` aliases for common types exist in the outer OpenImageIO scope:

```
TypeUnknown TypeFloat TypeColor TypePoint TypeVector TypeNormal
TypeMatrix33 TypeMatrix44 TypeMatrix TypeHalf
TypeInt TypeUInt TypeInt32 TypeUInt32 TypeInt64 TypeUInt64
TypeInt16 TypeUInt16 TypeInt8 TypeUInt8
TypeFloat2 TypeVector2 TypeVector2i TypeVector3i TypeFloat4
TypeString TypeTimeCode TypeKeyCode
TypeBox2 TypeBox2i TypeBox3 TypeBox3i
TypeRational TypePointer
```

The only types commonly used to store *pixel values* in image files are scalars of `UINT8`, `UINT16`, `float`, and `half` (the last only used by OpenEXR, to the best of our knowledge).

Note that the `TypeDesc` (which is also used for applications other than images) can describe many types not used by OpenImageIO. Please ignore this extra complexity; only the above simple types are understood by OpenImageIO as pixel storage data types, though a few others, including `string` and `MATRIX44` aggregates, are occasionally used for *metadata* for certain image file formats (see Sections `sec-imageoutput-metadata`, `sec-imageinput-metadata`, and the documentation of individual ImageIO plugins for details).

2.2 Non-owning string views: `string_view`

using `string_view` = `basic_string_view<char>`;

`string_view` is a synonym for a non-mutable `string_view<char>`.

template<class `CharT`, class `Traits` = `std::char_traits<CharT>`>>

class `basic_string_view`

A `string_view` is a non-owning, non-copying, non-allocating reference to a sequence of characters. It encapsulates both a character pointer and a length. This is analogous to C++17 `std::string_view`, but supports C++14.

Note: `string_view` is an alias for `basic_string_view<char>`.

A function that takes a string input (but does not need to alter the string in place) may use a `string_view` parameter and accept input that is any of `char*` (C string), string literal (constant char array), a `std::string` (C++ string), or `OIO ustring`. For all of these cases, no extra allocations are performed, and no extra copies of the string contents are performed (as they would be, for example, if the function took a `const std::string&` argument but was passed a `char*` or string literal).

Furthermore, a function that returns a copy or a substring of one of its inputs (for example, a `substr()`-like function) may return a `string_view` rather than a `std::string`, and thus generate its return value without any allocation or copying. Upon assignment to a `std::string` or `ustring`, it will properly auto-convert.

There are two important caveats to using this class:

- a. The `string_view` merely refers to characters owned by another string, so the `string_view` may not be used outside the lifetime of the string it refers to. Thus, `string_view` is great for parameter passing, but it's not a good idea to use a `string_view` to store strings in a data structure (unless you are really sure you know what you're doing).
- b. Because the run of characters that the `string_view` refers to may not be 0-terminated, it is important to distinguish between the `data()` method, which returns the pointer to the characters, and a proper `c_str()` method (which is NOT provided by `std::string_view`), which would be guaranteed to return a valid C string that is 0-terminated. Thus, if you want to pass the contents of a `string_view` to a function that expects a 0-terminated string (say, `fopen`), the usual practice is to call `fopen(std::string(my_string_view).c_str())`.

Public Functions

`inline constexpr basic_string_view()` noexcept

Default ctr.

`inline constexpr basic_string_view(const basic_string_view ©)`

Copy ctr.

`inline constexpr basic_string_view(const CharT *chars, size_t len)` noexcept

Construct from `char*` and length.

`inline constexpr basic_string_view(const CharT *chars)` noexcept

Construct from `char*`, use `strlen` to determine length.

`inline basic_string_view(const string &str)` noexcept

Construct from `std::string`. Remember that a `string_view` doesn't have its own copy of the characters, so don't use the `string_view` after the original string has been destroyed or altered.

`inline constexpr string str() const`

Convert a `string_view` to a `std::string`. NOTE: the `str()` method is not part of the C++17 `std::string_view`. If strict interchangeability with `std::string_view` is desired, you might prefer the equivalent idiom `std::string(sv)`.

`const CharT *c_str() const`

Explicitly request a 0-terminated string. USUALLY, this turns out to be just `data()`, with no significant added expense (because most uses of `string_view` are simple wrappers of C strings, C++ `std::string`, or

ustring — all of which are 0-terminated). But in the more rare case that the string_view represents a non-0-terminated substring, it will force an allocation and copy underneath.

Caveats:

- i. This is NOT going to be part of the C++17 std::string_view, so it's probably best to avoid this method if you want to have 100% drop-in compatibility with std::string_view.
- ii. It is NOT SAFE to use `c_str()` on a string_view whose last char is the end of an allocation — because that next char may only *coincidentally* be a '\0', which will cause `c_str()` to return the string start (thinking it's a valid C string, so why not just return its address?), if there's any chance that the subsequent char could change from 0 to non-zero during the use of the result of `c_str()`, and thus break the assumption that it's a valid C str.

```
inline operator std::basic_string<CharT, Traits>() const
```

Convert a string_view to a std::string.

```
inline constexpr bool empty() const noexcept
```

Is the *basic_string_view* empty, containing no characters?

```
inline constexpr const_reference operator[](size_type pos) const
```

Element access of an individual character (beware: no bounds checking!).

```
inline constexpr const_reference at(size_t pos) const
```

Element access with bounds checking and exception if out of bounds.

```
inline size_type find(basic_string_view s, size_t pos = 0) const noexcept
```

Find the first occurrence of substring s in *this, starting at position pos.

```
inline size_type find(CharT c, size_t pos = 0) const noexcept
```

Find the first occurrence of character c in *this, starting at position pos.

```
inline size_type rfind(basic_string_view s, size_t pos = npos) const noexcept
```

Find the last occurrence of substring s *this, but only those occurrences earlier than position pos.

```
inline size_type rfind(CharT c, size_t pos = npos) const noexcept
```

Find the last occurrence of character c in *this, but only those occurrences earlier than position pos.

2.3 Efficient unique strings: ustring

class **ustring**

A ustring is an alternative to char* or std::string for storing strings, in which the character sequence is unique (allowing many speed advantages for assignment, equality testing, and inequality testing).

The implementation is that behind the scenes there is a hash set of allocated strings, so the characters of each string are unique. A ustring itself is a pointer to the characters of one of these canonical strings. Therefore, assignment and equality testing is just a single 32- or 64-bit int operation, the only mutex is when a ustring is created from raw characters, and the only malloc is the first time each canonical ustring is created.

The internal table also contains a `std::string` version and the length of the string, so converting a `ustring` to a `std::string` (via `ustring::string()`) or querying the number of characters (via `ustring::size()` or `ustring::length()`) is extremely inexpensive, and does not involve creation/allocation of a new `std::string` or a call to `strlen`.

We try very hard to completely mimic the API of `std::string`, including all the constructors, comparisons, iterations, etc. Of course, the characters of a `ustring` are non-modifiable, so we do not replicate any of the non-const methods of `std::string`. But in most other ways it looks and acts like a `std::string` and so most templated algorithms that would work on a “const `std::string` &” will also work on a `ustring`.

Note that like a `char*`, but unlike a `std::string`, a `ustring` is not allowed to contain any embedded NUL (`'\0'`) characters. When constructing `ustrings` from a `std::string` or a `string_view`, the contents will be truncated at the point of any NUL character. This is done to ensure that `ustring::c_str()` refers to the same C-style character sequence as the `ustring` itself or `ustring::string()`.

Usage guidelines:

Compared to standard strings, `ustrings` have several advantages:

- Each individual `ustring` is very small — in fact, we guarantee that a `ustring` is the same size and memory layout as an ordinary `char*`.
- Storage is frugal, since there is only one allocated copy of each unique character sequence, throughout the lifetime of the program.
- Assignment from one `ustring` to another is just copy of the pointer; no allocation, no character copying, no reference counting.
- Equality testing (do the strings contain the same characters) is a single operation, the comparison of the pointer.
- Memory allocation only occurs when a new `ustring` is constructed from raw characters the FIRST time — subsequent constructions of the same string just finds it in the canonical string set, but doesn’t need to allocate new storage. Destruction of a `ustring` is trivial, there is no de-allocation because the canonical version stays in the set. Also, therefore, no user code mistake can lead to memory leaks.

But there are some problems, too. Canonical strings are never freed from the table. So in some sense all the strings “leak”, but they only leak one copy for each unique string that the program ever comes across. Also, creation of unique strings from raw characters is more expensive than for standard strings, due to hashing, table queries, and other overhead.

On the whole, `ustrings` are a really great string representation

- if you tend to have (relatively) few unique strings, but many copies of those strings;
- if the creation of strings from raw characters is relatively rare compared to copying or comparing to existing strings;
- if you tend to make the same strings over and over again, and if it’s relatively rare that a single unique character sequence is used only once in the entire lifetime of the program;
- if your most common string operations are assignment and equality testing and you want them to be as fast as possible;
- if you are doing relatively little character-by-character assembly of strings, string concatenation, or other “string manipulation” (other than equality testing).

`ustrings` are not so hot

- if your program tends to have very few copies of each character sequence over the entire lifetime of the program;

- if your program tends to generate a huge variety of unique strings over its lifetime, each of which is used only a short time and then discarded, never to be needed again;
- if you don't need to do a lot of string assignment or equality testing, but lots of more complex string manipulation.

Public Types

using **rep_t** = const char*

The underlying representation type.

using **hash_t** = uint64_t

The hash type.

Public Functions

inline constexpr **ustring**() noexcept

Default ctor for ustring; make an empty string.

inline explicit **ustring**(const char *str)

Construct a ustring from a null-terminated C string (char *).

inline explicit **ustring**(string_view str)

Construct a ustring from a string_view, which can be auto-converted from either a null-terminated C string (char *) or a C++ std::string.

inline **ustring**(const char *str, size_type pos, size_type n)

Construct a ustring from at most n characters of str, starting at position pos.

inline **ustring**(const char *str, size_type n)

Construct a ustring from the first n characters of str.

inline **ustring**(size_type n, char c)

Construct a ustring from n copies of character c.

inline **ustring**(const std::string &str, size_type pos, size_type n = npos)

Construct a ustring from an indexed substring of a std::string.

ustring(const *ustring* &str) noexcept = default

Copy construct a ustring from another ustring.

inline **ustring**(const *ustring* &str, size_type pos, size_type n = npos)

Construct a ustring from an indexed substring of a ustring.

inline explicit **ustring**(ustringhash hash)

Construct from a known ustringhash.

~ustring() noexcept = default

ustring destructor.

inline **operator string_view**() const noexcept

Conversion to an OIIO::string_view.

```
inline explicit operator std::string() const noexcept
    Conversion to std::string (explicit only!).

inline ustring &assign(const ustring &str)
    Assign a ustring to *this.

inline ustring &assign(const ustring &str, size_type pos, size_type n = npos)
    Assign a substring of a ustring to *this.

inline ustring &assign(const std::string &str)
    Assign a std::string to *this.

inline ustring &assign(const std::string &str, size_type pos, size_type n = npos)
    Assign a substring of a std::string to *this.

inline ustring &assign(const char *str)
    Assign a null-terminated C string (char*) to *this.

inline ustring &assign(const char *str, size_type n)
    Assign the first n characters of str to *this.

inline ustring &assign(size_type n, char c)
    Assign n copies of c to *this.

inline ustring &assign(string_view str)
    Assign a string_view to *this.

ustring &operator=(const ustring &str) noexcept = default
    Assign a ustring to another ustring.

inline ustring &operator=(const char *str)
    Assign a null-terminated C string (char *) to a ustring.

inline ustring &operator=(const std::string &str)
    Assign a C++ std::string to a ustring.

inline ustring &operator=(string_view str)
    Assign a string_view to a ustring.

inline ustring &operator=(char c)
    Assign a single char to a ustring.

inline const char *c_str() const noexcept
    Return a C string representation of a ustring.

inline const char *data() const noexcept
    Return a C string representation of a ustring.

inline const std::string &string() const noexcept
    Return a C++ std::string representation of a ustring.

inline void clear() noexcept
    Reset to an empty string.

inline size_t length() const noexcept
    Return the number of characters in the string.
```

```

inline hash_t hash() const noexcept
    Return a hashed version of the string.

inline ustringhash uhash() const noexcept
    Return a hashed version of the string.

inline size_t size() const noexcept
    Return the number of characters in the string.

inline bool empty() const noexcept
    Is the string empty &; i.e., is it nullptr or does it point to an empty string?

inline const_iterator begin() const noexcept
    Return a const_iterator that references the first character of the string.

inline const_iterator end() const noexcept
    Return a const_iterator that references the end of a traversal of the characters of the string.

inline const_reverse_iterator rbegin() const noexcept
    Return a const_reverse_iterator that references the last character of the string.

inline const_reverse_iterator rend() const noexcept
    Return a const_reverse_iterator that references the end of a reverse traversal of the characters of the string.

inline const_reference operator[](size_type pos) const noexcept
    Return a reference to the character at the given position. Note that it's up to the caller to be sure pos is
    within the size of the string.

inline size_type copy(char *s, size_type n, size_type pos = 0) const
    Dump into character array s the characters of this ustring, beginning with position pos and copying at most
    n characters.

inline ustring substr(size_type pos = 0, size_type n = npos) const
    Returns a substring of the ustring object consisting of n characters starting at position pos.

inline int compare(string_view str) const noexcept
    Return 0 if *this is lexicographically equal to str, -1 if *this is lexicographically earlier than str, 1 if *this is
    lexicographically after str.

inline int compare(const char *str) const noexcept
    Return 0 if *this is lexicographically equal to str, -1 if *this is lexicographically earlier than str, 1 if *this is
    lexicographically after str.

inline bool operator==(const ustring &str) const noexcept
    Test two ustrings for equality &; are they comprised of the same sequence of characters. Note that
    because ustrings are unique, this is a trivial pointer comparison, not a char-by-char loop as would be the
    case with a char* or a std::string.

inline bool operator!=(const ustring &str) const noexcept
    Test two ustrings for inequality &; are they comprised of different sequences of characters. Note that
    because ustrings are unique, this is a trivial pointer comparison, not a char-by-char loop as would be the
    case with a char* or a std::string.

inline bool operator==(const std::string &x) const noexcept
    Test a ustring (*this) for lexicographic equality with std::string x.

inline bool operator==(string_view x) const noexcept
    Test a ustring (*this) for lexicographic equality with string_view x.

```

```
inline bool operator==(const char *x) const noexcept
    Test a ustring (this) for lexicographic equality with char x.

inline bool operator!=(const std::string &x) const noexcept
    Test a ustring (*this) for lexicographic inequality with std::string x.

inline bool operator!=(string_view x) const noexcept
    Test a ustring (*this) for lexicographic inequality with string_view x.

inline bool operator!=(const char *x) const noexcept
    Test a ustring (this) for lexicographic inequality with char x.

inline bool operator<(const ustring &x) const noexcept
    Test for lexicographic 'less', comes in handy for lots of STL containers and algorithms.
```

Public Static Functions

```
template<typename ...Args>
static inline ustring sprintf(const char *fmt, const Args&... args)
    Construct a ustring in a printf-like fashion. In other words, something like: ustring s = ustring::sprintf("blah %d %g", (int)foo, (float)bar); The argument list is fully typesafe. The formatting of the string will always use the classic "C" locale conventions (in particular, '.' as decimal separator for float values).

template<typename ...Args>
static inline ustring fmtformat(const char *fmt, const Args&... args)
    Construct a ustring in a fmt::format-like fashion. In other words, something like: ustring s = ustring::fmtformat("blah {} {}", (int)foo, (float)bar); The argument list is fully typesafe. The formatting of the string will always use the classic "C" locale conventions (in particular, '.' as decimal separator for float values).

template<typename ...Args>
static inline ustring format(const char *fmt, const Args&... args)
    NOTE: Semi-DEPRECATED! This will someday switch to behave like fmt::format (or future std::format) but for now, it is back compatible and equivalent to sprintf.

static ustring concat(string_view s, string_view t)
    Concatenate two strings, returning a ustring, implemented carefully to not perform any redundant copies or allocations.

static std::string getstats(bool verbose = true)
    Return the statistics output as a string.

static size_t memory()
    Return the amount of memory consumed by the ustring table.

static size_t total_ustrings()
    Return the total number of ustrings in the internal table.

static size_t hash_collisions(std::vector<ustring> *collisions = nullptr)
    Return the total number ustrings that have the exact hash as another ustring. If collisions is passed, store all the colliding ustrings in the vector.
```

```
static const char *make_unique(string_view str)
```

Given a `string_view`, return a pointer to the unique version kept in the internal table (creating a new table entry if we haven't seen this sequence of characters before). N.B.: this is equivalent to `ustring(str).c_str()`. It's also the routine that is used directly by `ustring`'s internals to generate the canonical unique copy of the characters.

```
static inline bool is_unique(const char *str)
```

Is this character pointer a unique `ustring` representation of those characters? Useful for diagnostics and debugging.

```
static inline ustring from_unique(const char *unique)
```

Create a `ustring` from characters guaranteed to already be `ustring`-clean, without having to run through the hash yet again. Use with extreme caution!!!

```
static ustring from_hash(hash_t hash)
```

Return the `ustring` corresponding to the given hash, or the empty `ustring()` if there is no registered `ustring` with that hash. Note that if there are multiple `ustrings` with the same hash, this will return the first one it finds in the table.

Friends

```
inline friend int compare(const std::string &a, const ustring &b) noexcept
```

Return 0 if `a` is lexicographically equal to `b`, -1 if `a` is lexicographically earlier than `b`, 1 if `a` is lexicographically after `b`.

```
inline friend bool operator==(const std::string &a, const ustring &b) noexcept
```

Test for lexicographic equality between `std::string` `a` and `ustring` `b`.

```
inline friend bool operator==(string_view a, const ustring &b) noexcept
```

Test for lexicographic equality between `string_view` `a` and `ustring` `b`.

```
inline friend bool operator==(const char *a, const ustring &b) noexcept
```

Test for lexicographic equality between `char*` `a` and `ustring` `b`.

```
inline friend bool operator!=(const std::string &a, const ustring &b) noexcept
```

Test for lexicographic inequality between `std::string` `a` and `ustring` `b`.

```
inline friend bool operator!=(string_view a, const ustring &b) noexcept
```

Test for lexicographic inequality between `string_view` `a` and `ustring` `b`.

```
inline friend bool operator!=(const char *a, const ustring &b) noexcept
```

Test for lexicographic inequality between `char*` `a` and `ustring` `b`.

```
inline friend std::ostream &operator<<(std::ostream &out, const ustring &str)
```

Generic stream output of a `ustring`.

```
struct TableRep
```

2.4 Non-owning array views: `span` / `cspan`

```
template<typename T, span_size_t Extent = dynamic_extent>
```

```
class span
```

`span<T>` is a non-owning, non-copying, non-allocating reference to a contiguous array of `T` objects of known length. A ‘span’ encapsulates both a pointer and a length, and thus is a safer way of passing pointers around (because the function called knows how long the array is). A function that might ordinarily take a `T*` and a length could instead just take a `span<T>`.

A `span<T>` is mutable (the values in the array may be modified). A non-mutable (i.e., read-only) reference would be `span<const T>`. Thus, a function that might ordinarily take a `const T*` and a length could instead take a `span<const T>`.

For convenience, we also define `cspan<T>` as equivalent to `span<const T>`.

A `span` may be initialized explicitly from a pointer and length, by initializing with a `std::vector<T>`, or by initializing with a constant (treated as an array of length 1). For all of these cases, no extra allocations are performed, and no extra copies of the array contents are made.

Important caveat: The `span` merely refers to items owned by another array, so the `span` should not be used beyond the lifetime of the array it refers to. Thus, `span` is great for parameter passing, but it’s not a good idea to use a `span` to store values in a data structure (unless you are really sure you know what you’re doing).

Subclassed by `OIO::ParamValueSpan`

Public Functions

```
constexpr span() noexcept = default
```

Default constructor — the span will be `{nullptr, 0}`.

```
template<class U, span_size_t N>
```

```
inline constexpr span(const span<U, N> &copy) noexcept
```

Copy constructor (copies the span pointer and length, NOT the data).

```
constexpr span(const span &copy) noexcept = default
```

Copy constructor (copies the span pointer and length, NOT the data).

```
inline constexpr span(pointer data, size_type size) noexcept
```

Construct from `T*` and length.

```
inline constexpr span(pointer b, pointer e) noexcept
```

Construct from begin and end pointers.

```
inline constexpr span(T &data)
```

Construct from a single `T&`.

```
template<size_t N>
```

```
inline constexpr span(T (&data)[N]) noexcept
```

Construct from a fixed-length C array. Template magic automatically finds the length from the declared type of the array.

```
template<class Allocator>
```

```
inline constexpr span(std::vector<T, Allocator> &v)
```

Construct from `std::vector<T>`.

```
template<class Allocator>
```

```

inline span(const std::vector<value_type, Allocator> &v) noexcept
    Construct from const std::vector<T>. This turns const std::vector<T> into a span<const T>
    (the span isn't const, but the data it points to will be).

template<size_t N>
inline constexpr span(std::array<value_type, N> &arr) noexcept
    Construct from mutable element std::array.

template<size_t N>
inline constexpr span(const std::array<value_type, N> &arr) noexcept
    Construct from read-only element std::array.

inline constexpr span(std::initializer_list<T> il) noexcept
    Construct a span from an initializer_list.

constexpr span &operator=(const span &copy) = default
    Assignment copies the pointer and length, not the data.

template<size_type Count>
inline constexpr span<element_type, Count> first() const
    Subview containing the first Count elements of the span.

template<size_type Count>
inline constexpr span<element_type, Count> last() const
    Subview containing the last Count elements of the span.

```

Additionally, there is a convenience template:

```

template<typename T>
using cspan = span<const T>
    cspan<T> is a synonym for a non-mutable span<const T>.

```

2.5 Rectangular region of interest: ROI

struct **ROI**

ROI is a small helper struct describing a rectangular region of interest in an image. The region is [xbegin,xend) x [begin,yend) x [zbegin,zend), with the “end” designators signifying one past the last pixel in each dimension, a la STL style.

ROI data members

The data members are:

```
int xbegin, xend, ybegin, yend, zbegin, zend;  
int chbegin, chend;
```

These describe the spatial extent [xbegin,xend) x [ybegin,yend) x [zbegin,zend) And the channel extent: [chbegin,chend)

Spatial size functions.

The width, height, and depth of the region.

```
inline constexpr int width() const noexcept  
    Height.
```

```
inline constexpr int height() const noexcept  
    Width.
```

```
inline constexpr int depth() const noexcept  
    Depth.
```

Public Functions

```
inline constexpr ROI() noexcept  
    Default constructor is an undefined region. Note that this is also interpreted as All().
```

```
inline constexpr ROI(int xbegin, int xend, int ybegin, int yend, int zbegin = 0, int zend = 1, int chbegin = 0, int  
    chend = 10000) noexcept  
    Constructor with an explicitly defined region.
```

```
inline constexpr bool defined() const noexcept  
    Is a region defined?
```

```
inline constexpr int nchannels() const noexcept  
    Number of channels in the region. Beware &#8212; this defaults to a huge number, and to be meaningful  
    you must consider std::min (imagebuf.nchannels(), roi.nchannels()).
```

```
inline constexpr imagesize_t npixels() const noexcept  
    Total number of pixels in the region.
```

```
inline constexpr bool contains(int x, int y, int z = 0, int ch = 0) const noexcept  
    Test if the coordinate is within the ROI.
```

```
inline constexpr bool contains(const ROI &other) const noexcept  
    Test if another ROI is entirely within our ROI.
```

Public Static Functions

static inline constexpr *ROI* **All**() noexcept

All() is an alias for the default constructor, which indicates that it means “all” of the image, or no region restriction. For example, float myfunc (ImageBuf &buf, *ROI* roi = *ROI::All*(); Note that this is equivalent to: float myfunc (ImageBuf &buf, *ROI* roi = {});

Friends

inline friend constexpr friend bool operator== (const *ROI* &a, const *ROI* &b) noexcept

Test equality of two ROIs.

inline friend constexpr friend bool operator!= (const *ROI* &a, const *ROI* &b) noexcept

Test inequality of two ROIs.

inline friend std::ostream &operator<<(std::ostream &out, const *ROI* &roi)

Stream output of the range.

In addition, there are several related helper functions that involve ROI:

inline constexpr *ROI* OIIO::roi_union(const *ROI* &A, const *ROI* &B) noexcept

Union of two regions, the smallest region containing both.

inline constexpr *ROI* OIIO::roi_intersection(const *ROI* &A, const *ROI* &B) noexcept

Intersection of two regions.

ROI get_roi(const ImageSpec &spec)

ROI get_roi_full(const ImageSpec &spec)

Return the ROI describing spec’s pixel data window (the x, y, z, width, height, depth fields) or the full (display) window (the full_x, full_y, full_z, full_width, full_height, full_depth fields), respectively.

void set_roi(const ImageSpec &spec, const *ROI* &newroi)

void set_roi_full(const ImageSpec &spec, const *ROI* &newroi)

Alters the spec so to make its pixel data window or the full (display) window match newroi.

2.6 Image Specification: ImageSpec

An ImageSpec is a structure that describes the complete format specification of a single image. It contains:

- The image resolution (number of pixels) and origin. This specifies what is often called the “pixel data window.”
- The full size and offset of an abstract “full” or “display” window. Differing full and data windows can indicate that the pixels are a crop region or a larger image, or contain overscan pixels.
- Whether the image is organized into *tiles*, and if so, the tile size.
- The *native data format* of the pixel values (e.g., float, 8-bit integer, etc.).
- The number of color channels in the image (e.g., 3 for RGB images), names of the channels, and whether any particular channels represent *alpha* and *depth*.
- A user-extensible (and format-extensible) list of any other arbitrarily-named and -typed data that may help describe the image or its disk representation.

The remainder of this section describes the C++ API for ImageSpec. See Section *ImageSpec* for the corresponding Python bindings.

class **ImageSpec**

ImageSpec describes the data format of an image; dimensions, layout, number and meanings of image channels.

The `width`, `height`, `depth` are the size of the data of this image, i.e., the number of pixels in each dimension. A `depth` greater than 1 indicates a 3D “volumetric” image. The `x`, `y`, `z` fields indicate the *origin* of the pixel data of the image. These default to (0,0,0), but setting them differently may indicate that this image is offset from the usual origin. Therefore the pixel data are defined over pixel coordinates [`x` ... `x+width-1`] horizontally, [`y` ... `y+height-1`] vertically, and [`z` ... `z+depth-1`] in depth.

The analogous `full_width`, `full_height`, `full_depth` and `full_x`, `full_y`, `full_z` fields define a “full” or “display” image window over the region [`full_x` ... `full_x+full_width-1`] horizontally, [`full_y` ... `full_y+full_height-1`] vertically, and [`full_z` ... `full_z+full_depth-1`] in depth.

Having the full display window different from the pixel data window can be helpful in cases where you want to indicate that your image is a *crop window* of a larger image (if the pixel data window is a subset of the full display window), or that the pixels include *overscan* (if the pixel data is a superset of the full display window), or may simply indicate how different non-overlapping images piece together.

For tiled images, `tile_width`, `tile_height`, and `tile_depth` specify that the image is stored in a file organized into rectangular *tiles* of these dimensions. The default of 0 value for these fields indicates that the image is stored in scanline order, rather than as tiles.

ImageSpec data members

The *ImageSpec* contains data fields for the values that are required to describe nearly any image, and an extensible list of arbitrary attributes that can hold metadata that may be user-defined or specific to individual file formats.

Here are the hard-coded data fields:

int x
origin (upper left corner) of pixel data

int y
origin (upper left corner) of pixel data

int z
origin (upper left corner) of pixel data

int width
width of the pixel data window

int height
height of the pixel data window

int depth
depth of pixel data, >1 indicates a “volume”

int **full_x**
origin of the full (display) window

int **full_y**
origin of the full (display) window

int **full_z**
origin of the full (display) window

int **full_width**
width of the full (display) window

int **full_height**
height of the full (display) window

int **full_depth**
depth of the full (display) window

int **tile_width**
tile width (0 for a non-tiled image)

int **tile_height**
tile height (0 for a non-tiled image)

int **tile_depth**
tile depth (0 for a non-tiled image, 1 for a non-volume image)

int **nchannels**
number of image channels, e.g., 4 for RGBA

TypeDesc format

Data format of the channels. Describes the native format of the pixel data values themselves, as a *TypeDesc*. Typical values would be *TypeDesc::UINT8* for 8-bit unsigned values, *TypeDesc::FLOAT* for 32-bit floating-point values, etc.

std::vector<*TypeDesc*> **channelformats**

Optional per-channel data formats. If all channels of the image have the same data format, that will be described by **format** and **channelformats** will be empty (zero length). If there are different data formats for each channel, they will be described in the **channelformats** vector, and the **format** field will indicate a single default data format for applications that don't wish to support per-channel formats (usually this will be the format of the channel that has the most precision).

std::vector<std::string> **channelnames**

The names of each channel, in order. Typically this will be "R", "G", "B", "A" (alpha), "Z" (depth), or other arbitrary names.

int **alpha_channel**

The index of the channel that represents *alpha* (pixel coverage and/or transparency). It defaults to -1 if no alpha channel is present, or if it is not known which channel represents alpha.

int **z_channel**

The index of the channel that represents *z* or *depth* (from the camera). It defaults to -1 if no depth channel is present, or if it is not known which channel represents depth.

bool **deep**

True if the image contains deep data. If **true**, this indicates that the image describes contains “deep” data consisting of multiple samples per pixel. If **false**, it’s an ordinary image with one data value (per channel) per pixel.

ParamValueList **extra_attribs**

A list of arbitrarily-named and arbitrarily-typed additional attributes of the image, for any metadata not described by the hard-coded fields described above. This list may be manipulated with the [attribute\(\)](#) and [find_attribute\(\)](#) methods.

Public Functions

ImageSpec(*TypeDesc* format = *TypeDesc::UNKNOWN*) noexcept

Constructor: given just the data format, set all other fields to something reasonable.

inline **ImageSpec**(string_view format) noexcept

Constructor: given just the data format (as any type name recognized by the [TypeDesc](#) constructor), set all other fields to something reasonable.

ImageSpec(int xres, int yres, int nchans, *TypeDesc* fmt = TypeUInt8) noexcept

Constructs an [ImageSpec](#) with the given x and y resolution, number of channels, and pixel data format.

All other fields are set to the obvious defaults — the image is an ordinary 2D image (not a volume), the image is not offset or a crop of a bigger image, the image is scanline-oriented (not tiled), channel names are “R”, “G”, “B” and “A” (up to and including 4 channels, beyond that they are named “channel *n*”), the fourth channel (if it exists) is assumed to be alpha.

inline **ImageSpec**(int xres, int yres, int nchans, string_view fmt) noexcept

Construct an [ImageSpec](#) with the given x and y resolution, number of channels, and pixel data format name (as any type name recognized by the [TypeDesc](#) constructor).

explicit **ImageSpec**(const *ROI* &roi, *TypeDesc* fmt = TypeUInt8) noexcept

Construct an [ImageSpec](#) whose dimensions (both data and “full”) and number of channels are given by the *ROI*, pixel data type by *fmt*, and other fields are set to their default values.

inline explicit **ImageSpec**(const *ROI* &roi, string_view fmt) noexcept

Construct an [ImageSpec](#) from an *ROI* giving dimensions, and the name of a data type that will be recognized by the [TypeDesc](#) constructor.

void **set_format**(*TypeDesc* fmt) noexcept

Set the data format, and clear any per-channel format information in `channelformats`.

inline void **set_format**(string_view fmt) noexcept

Set the data format, and clear any per-channel format information in `channelformats`. The *fmt* may be a string such as “uint8”, or any other type name recognized by the [TypeDesc](#) constructor.

void **default_channel_names()** noexcept

Sets the `channelNames` to reasonable defaults for the number of channels. Specifically, channel names are set to “R”, “G”, “B,” and “A” (up to and including 4 channels, beyond that they are named “channel*n”).

inline size_t **channel_bytes()** const noexcept

Returns the number of bytes comprising each channel of each pixel (i.e., the size of a single value of the type described by the `format` field).

size_t **channel_bytes**(int chan, bool native = false) const noexcept

Return the number of bytes needed for the single specified channel. If `native` is false (default), compute the size of one channel of `this->format`, but if `native` is true, compute the size of the channel in terms of the “native” data format of that channel as stored in the file.

size_t **pixel_bytes**(bool native = false) const noexcept

Return the number of bytes for each pixel (counting all channels). If `native` is false (default), assume all channels are in `this->format`, but if `native` is true, compute the size of a pixel in the “native” data format of the file (these may differ in the case of per-channel formats).

size_t **pixel_bytes**(int chbegin, int chend, bool native = false) const noexcept

Return the number of bytes for just the subset of channels in each pixel described by `[chbegin, chend)`. If `native` is false (default), assume all channels are in `this->format`, but if `native` is true, compute the size of a pixel in the “native” data format of the file (these may differ in the case of per-channel formats).

imagesize_t **scanline_bytes**(bool native = false) const noexcept

Returns the number of bytes comprising each scanline, i.e., `pixel_bytes(native) * width`. This will return `std::numeric_limits<imagesize_t>::max()` in the event of an overflow where it’s not representable in an `imagesize_t`.

imagesize_t **tile_pixels()** const noexcept

Return the number of pixels comprising a tile (or 0 if it is not a tiled image). This will return `std::numeric_limits<imagesize_t>::max()` in the event of an overflow where it’s not representable in an `imagesize_t`.

imagesize_t **tile_bytes**(bool native = false) const noexcept

Returns the number of bytes comprising an image tile, i.e., `pixel_bytes(native) * tile_width * tile_height * tile_depth`. If `native` is false (default), assume all channels are in `this->format`, but if `native` is true, compute the size of a pixel in the “native” data format of the file (these may differ in the case of per-channel formats).

imagesize_t **image_pixels()** const noexcept

Return the number of pixels for an entire image. This will return `std::numeric_limits<imagesize_t>::max()` in the event of an overflow where it’s not representable in an `imagesize_t`.

imagesize_t **image_bytes**(bool native = false) const noexcept

Returns the number of bytes comprising an entire image of these dimensions, i.e., `pixel_bytes(native) * width * height * depth`. This will return `std::numeric_limits<image size_t>::max()` in the event of an overflow where it’s not representable in an `imagesize_t`. If `native` is false (default), assume all channels are in `this->format`, but if `native` is true, compute the size of a pixel in the “native” data format of the file (these may differ in the case of per-channel formats).

inline bool **size_t_safe()** const noexcept

Verify that on this platform, a `size_t` is big enough to hold the number of bytes (and pixels) in a scanline, a tile, and the whole image. If this returns false, the image is much too big to allocate and read all at once, so client apps beware and check these routines for overflows!

void **attribute**(string_view name, *TypeDesc* type, const void *value)

Add a metadata attribute to `extra_attribs`, with the given name and data type. The value pointer specifies the address of the data to be copied.

inline void **attribute**(string_view name, unsigned int value)

Add an unsigned int attribute to `extra_attribs`.

inline void **attribute**(string_view name, int value)

Add an int attribute to `extra_attribs`.

inline void **attribute**(string_view name, float value)

Add a float attribute to `extra_attribs`.

void **attribute**(string_view name, string_view value)

Add a string attribute to `extra_attribs`.

void **attribute**(string_view name, *ustring* value)

Add a string attribute (passed as a *ustring*) to `extra_attribs`.

void **attribute**(string_view name, *TypeDesc* type, string_view value)

Parse a string containing a textual representation of a value of the given type, and add that as an attribute to `extra_attribs`. Example:

```
spec.attribute ("temperature", TypeFloat, "-273.15");
```

void **erase_attribute**(string_view name, *TypeDesc* searchtype = *TypeDesc::UNKNOWN*, bool casesensitive = false)

Searches `extra_attribs` for any attributes matching name (as a regular expression), removing them entirely from `extra_attribs`. If searchtype is anything other than *TypeDesc::UNKNOWN*, matches will be restricted only to attributes with the given type. The name comparison will be case-sensitive if casesensitive is true, otherwise in a case-insensitive manner.

ParamValue ***find_attribute**(string_view name, *TypeDesc* searchtype = *TypeDesc::UNKNOWN*, bool casesensitive = false)

Searches `extra_attribs` for an attribute matching name, returning a pointer to the attribute record, or NULL if there was no match. If searchtype is anything other than *TypeDesc::UNKNOWN*, matches will be restricted only to attributes with the given type. The name comparison will be exact if casesensitive is true, otherwise in a case-insensitive manner if caseinsensitive is false.

const ParamValue ***find_attribute**(string_view name, ParamValue &tmpparam, *TypeDesc* searchtype = *TypeDesc::UNKNOWN*, bool casesensitive = false) const

Search for the named attribute and return the pointer to its ParamValue record, or NULL if not found. This variety of `find_attribute()` can retrieve items such as "width", which are data members of the *ImageSpec*, but not in `extra_attribs`. The tmpparam is a storage area owned by the caller, which is used as temporary buffer in cases where the information does not correspond to an actual `extra_attribs` (in this case, the return value will be &tmpparam). The extra names it understands are:

- "x" "y" "z" "width" "height" "depth" "full_x" "full_y" "full_z" "full_width" "full_height" "full_depth"

Returns the *ImageSpec* fields of those names (despite the fact that they are technically not arbitrary named attributes in `extra_attribs`). All are of type int.

- "datawindow"

Without a type, or if requested explicitly as an `int[4]`, returns the OpenEXR-like pixel data min and max coordinates, as a 4-element integer array: { `x`, `y`, `x+width-1`, `y+height-1` }. If instead you specifically request as an `int[6]`, it will return the volumetric data window, { `x`, `y`, `z`, `x+width-1`, `y+height-1`, `z+depth-1` }.

- "displaywindow"

Without a type, or if requested explicitly as an `int[4]`, returns the OpenEXR-like pixel display min and max coordinates, as a 4-element integer array: { `full_x`, `full_y`, `full_x+full_width-1`, `full_y+full_height-1` }. If instead you specifically request as an `int[6]`, it will return the volumetric display window, { `full_x`, `full_y`, `full_z`, `full_x+full_width-1`, `full_y+full_height-1`, `full_z+full_depth-1` }.

EXAMPLES

```
ImageSpec spec;           // has the info
Imath::Box2i dw;          // we want the displaywindow here
ParamValue tmp;           // so we can retrieve pseudo-values
TypeDesc int4("int[4]");  // Equivalent: TypeDesc int4(TypeDesc::INT,4);
const ParamValue* p = spec.find_attribute("displaywindow", int4);
if (p)
    dw = Imath::Box2i(p->get<int>(0), p->get<int>(1),
                     p->get<int>(2), p->get<int>(3));

p = spec.find_attribute("temperature", TypeFloat);
if (p)
    float temperature = p->get<float>();
```

TypeDesc **getattributetype**(string_view name, bool casesensitive = false) const

If the named attribute can be found in the *ImageSpec*, return its data type. If no such attribute exists, return *TypeUnknown*.

This was added in version 2.1.

bool **getattribute**(string_view name, *TypeDesc* type, void *value, bool casesensitive = false) const

If the *ImageSpec* contains the named attribute and its type matches *type*, copy the attribute value into the memory pointed to by *val* (it is up to the caller to ensure there is enough space) and return *true*. If no such attribute is found, or if it doesn't match the type, return *false* and do not modify *val*.

EXAMPLES:

```
ImageSpec spec;
...
// Retrieving an integer attribute:
int orientation = 0;
spec.getattribute("orientation", TypeInt, &orientation);

// Retrieving a string attribute with a char*:
const char* compression = nullptr;
spec.getattribute("compression", TypeString, &compression);

// Alternately, retrieving a string with a ustring:
ustring compression;
spec.getattribute("compression", TypeString, &compression);
```

Note that when passing a string, you need to pass a pointer to the `char*`, not a pointer to the first character. Also, the `char*` will end up pointing to characters owned by the *ImageSpec*; the caller does not need to

ever free the memory that contains the characters.

This was added in version 2.1.

int **get_int_attribute**(string_view name, int defaultval = 0) const

Retrieve the named metadata attribute and return its value as an `int`. Any integer type will convert to `int` by truncation or expansion, string data will be parsed into an `int` if its contents consist of the text representation of one integer. Floating point data will not succeed in converting to an `int`. If no such metadata exists, or are of a type that cannot be converted, the `defaultval` will be returned.

float **get_float_attribute**(string_view name, float defaultval = 0) const

Retrieve the named metadata attribute and return its value as a `float`. Any integer or floating point type will convert to `float` in the obvious way (like a C cast), and so will string metadata if its contents consist of the text representation of one floating point value. If no such metadata exists, or are of a type that cannot be converted, the `defaultval` will be returned.

string_view **get_string_attribute**(string_view name, string_view defaultval = string_view()) const

Retrieve any metadata attribute, converted to a string. If no such metadata exists, the `defaultval` will be returned.

std::string **serialize**(SerialFormat format, SerialVerbose verbose = SerialDetailed) const

Returns, as a string, a serialized version of the *ImageSpec*. The format may be either `ImageSpec::SerialText` or `ImageSpec::SerialXML`. The `verbose` argument may be one of: `ImageSpec::SerialBrief` (just resolution and other vital statistics, one line for `SerialText`, `ImageSpec::SerialDetailed` (contains all metadata in original form), or `ImageSpec::SerialDetailedHuman` (contains all metadata, in many cases with human-readable explanation).

std::string **to_xml**() const

Converts the contents of the *ImageSpec* as an XML string.

void **from_xml**(const char *xml)

Populates the fields of the *ImageSpec* based on the XML passed in.

std::pair<string_view, int> **decode_compression_metadata**(string_view defaultcomp = "", int defaultqual = -1) const

Hunt for the “Compression” and “CompressionQuality” settings in the spec and turn them into the compression name and quality. This handles compression name/qual combos of the form “name:quality”.

inline bool **valid_tile_range**(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend) noexcept

Helper function to verify that the given pixel range exactly covers a set of tiles. Also returns false if the spec indicates that the image isn’t tiled at all.

inline *TypeDesc* **channelformat**(int chan) const

Return the channelformat of the given channel. This is safe even if `channelformats` is not filled out.

inline string_view **channel_name**(int chan) const

Return the channel name of the given channel. This is safe even if `channelnames` is not filled out.

inline void **get_channelformats**(std::vector<*TypeDesc*> &formats) const

Fill in an array of channel formats describing all channels in the image. (Note that this differs slightly from the member data `channelformats`, which is empty if there are not separate per-channel formats.)

int **channelindex**(string_view name) const

Return the index of the channel with the given name, or -1 if no such channel is present in `channelnames`.

inline *ROI* **roi**() const noexcept

Return pixel data window for this *ImageSpec* expressed as a *ROI*.

inline *ROI* **roi_full**() const noexcept

Return full/display window for this *ImageSpec* expressed as a *ROI*.

inline void **set_roi**(const *ROI* &r) noexcept

Set pixel data window parameters (x, y, z, width, height, depth) for this *ImageSpec* from an *ROI*. Does NOT change the channels of the spec, regardless of r.

inline void **set_roi_full**(const *ROI* &r) noexcept

Set full/display window parameters (full_x, full_y, full_z, full_width, full_height, full_depth) for this *ImageSpec* from an *ROI*. Does NOT change the channels of the spec, regardless of r.

inline void **copy_dimensions**(const *ImageSpec* &other)

Copy from *other* the image dimensions (x, y, z, width, height, depth, full*, nchannels, format) and data types. It does *not* copy arbitrary named metadata or channel names (thus, for an *ImageSpec* with lots of metadata, it is much less expensive than copying the whole thing with `operator=()`).

void **set_colorspace**(string_view name)

Set the metadata to presume that color space is *name* (or to assume nothing about the color space if *name* is empty). The core operation is to set the “oiio:ColorSpace” attribute, but it also removes or alters several other attributes that may hint color space in ways that might be contradictory or no longer true.

Version

2.5

inline bool **undefined**() const noexcept

Returns `true` for a newly initialized (undefined) *ImageSpec*. (Designated by no channels and undefined data type — true of the uninitialized state of an *ImageSpec*, and presumably not for any *ImageSpec* that is useful or purposefully made.)

inline AttrDelegate<*ImageSpec*> **operator[]**(string_view name)

Array indexing by string will create an AttrDelegate that enables a convenient shorthand for adding and retrieving values from the spec:

- i. Assigning to the delegate adds a metadata attribute:

```
ImageSpec spec;
spec["foo"] = 42;           // int
spec["pi"] = float(M_PI);  // float
spec["oiio:ColorSpace"] = "sRGB"; // string
spec["cameratoworld"] = Imath::Matrix44(...); // matrix
```

Be very careful, the attribute’s type will be implied by the C++ type of what you assign.

- ii. String data may be retrieved directly, and for other types, the delegate supports a `get<T>()` that retrieves an item of type T:

```
std::string colorspace = spec["oiio:ColorSpace"];
int dither = spec["oiio:dither"].get<int>();
```

This was added in version 2.1.

Public Static Functions

static inline void **auto_stride**(stride_t &xstride, stride_t &ystride, stride_t &zstride, stride_t channelsize, int nchannels, int width, int height) noexcept

Adjust the stride values, if set to AutoStride, to be the right sizes for contiguous data with the given format, channels, width, height.

static inline void **auto_stride**(stride_t &xstride, stride_t &ystride, stride_t &zstride, *TypeDesc* format, int nchannels, int width, int height) noexcept

Adjust the stride values, if set to AutoStride, to be the right sizes for contiguous data with the given format, channels, width, height.

static inline void **auto_stride**(stride_t &xstride, *TypeDesc* format, int nchannels) noexcept

Adjust xstride, if set to AutoStride, to be the right size for contiguous data with the given format and channels.

static std::string **metadata_val**(const ParamValue &p, bool human = false)

For a given parameter p, format the value nicely as a string. If human is true, use especially human-readable explanations (units, or decoding of values) for certain known metadata.

2.7 “Deep” pixel data: DeepData

class **DeepData**

A *DeepData* holds the contents of an image of ‘deep’ pixels (multiple depth samples per pixel).

Public Functions

DeepData()

Construct an empty *DeepData*.

DeepData(const *ImageSpec* &spec)

Construct and init from an *ImageSpec*.

DeepData(const *DeepData* &src)

Copy constructor.

DeepData(const *DeepData* &src, *cspan*<*TypeDesc*> channeltypes)

Copy constructor with change of channel types.

DeepData(*DeepData* &&src)

Move constructor.

const *DeepData* &**operator=**(const *DeepData* &d)

Copy assignment.

void **clear**()

Reset the *DeepData* to be equivalent to its empty initial state.

void **free**()

In addition to performing the tasks of *clear*(), also ensure that all allocated memory has been truly freed.

void **init**(int64_t npix, int nchan, *cspan*<*TypeDesc*> channeltypes, *cspan*<std::string> channelnames)

Initialize the *DeepData* with the specified number of pixels, channels, channel types, and channel names, and allocate memory for all the data.

void **init**(const *ImageSpec* &spec)

Initialize the *DeepData* based on the *ImageSpec*'s total number of pixels, number and types of channels. At this stage, all pixels are assumed to have 0 samples, and no sample data is allocated.

bool **initialized**() const

Is the *DeepData* initialized?

bool **allocated**() const

Has the *DeepData* fully allocated? If no, it is still very inexpensive to call *set_capacity*().

int64_t **pixels**() const

Retrieve the total number of pixels.

int **channels**() const

Retrieve the number of channels.

string_view **channelname**(int c) const

Return the name of channel c.

TypeDesc **channeltype**(int c) const

Retrieve the data type of channel c.

size_t **channelsize**(int c) const

Return the size (in bytes) of one sample datum of channel c.

size_t **samplesize**() const

Return the size (in bytes) for all channels of one sample.

bool **same_channeltypes**(const *DeepData* &other) const

Does this *DeepData* have the same channel types as other?

int **samples**(int64_t pixel) const

Retrieve the number of samples for the given pixel index.

void **set_samples**(int64_t pixel, int samps)

Set the number of samples for the given pixel. This must be called after *init*().

void **set_all_samples**(*cspan*<unsigned int> samples)

Set the number of samples for all pixels. The *samples.size()* is required to match *pixels*().

void **set_capacity**(int64_t pixel, int samps)

Set the capacity of samples for the given pixel. This must be called after *init*().

int **capacity**(int64_t pixel) const

Retrieve the capacity (number of allocated samples) for the given pixel index.

void **insert_samples**(int64_t pixel, int samplepos, int n = 1)
Insert *n* samples of the specified pixel, beginning at the sample position index. After insertion, the new samples will have uninitialized values.

void **erase_samples**(int64_t pixel, int samplepos, int n = 1)
Erase *n* samples of the specified pixel, beginning at the sample position index.

float **deep_value**(int64_t pixel, int channel, int sample) const
Retrieve the value of the given pixel, channel, and sample index, cast to a `float`.

uint32_t **deep_value_uint**(int64_t pixel, int channel, int sample) const
Retrieve the value of the given pixel, channel, and sample index, cast to a `uint32`.

void **set_deep_value**(int64_t pixel, int channel, int sample, float value)
Set the value of the given pixel, channel, and sample index, for floating-point channels.

void **set_deep_value**(int64_t pixel, int channel, int sample, uint32_t value)
Set the value of the given pixel, channel, and sample index, for integer channels.

void ***data_ptr**(int64_t pixel, int channel, int sample)
Retrieve the pointer to a given pixel/channel/sample, or `NULL` if there are no samples for that pixel. Use with care, and note that calls to `insert_samples` and `erase_samples` can invalidate pointers returned by prior calls to `data_ptr`.

void **get_pointers**(std::vector<void*> &pointers) const
Fill in the vector with pointers to the start of the first channel for each pixel.

bool **copy_deep_sample**(int64_t pixel, int sample, const *DeepData* &src, int64_t srcpixel, int srcsample)
Copy a deep sample from `src` to this *DeepData*. They must have the same channel layout. Return `true` if ok, `false` if the operation could not be performed.

bool **copy_deep_pixel**(int64_t pixel, const *DeepData* &src, int64_t srcpixel)
Copy an entire deep pixel from `src` to this *DeepData*, completely replacing any pixel data for that pixel. They must have the same channel layout. Return `true` if ok, `false` if the operation could not be performed.

bool **split**(int64_t pixel, float depth)
Split all samples of that pixel at the given depth `zsplit`. Samples that span *z* (i.e. $z < zsplit < zback$) will be split into two samples with depth ranges $[z, zsplit]$ and $[zsplit, zback]$ with appropriate changes to their color and alpha values. Samples not spanning `zsplit` will remain intact. This operation will have no effect if there are not *Z* and *Zback* channels present. Return `true` if any splits occurred, `false` if the pixel was not modified.

void **sort**(int64_t pixel)
Sort the samples of the pixel by their *Z* depth.

void **merge_overlaps**(int64_t pixel)
Merge any adjacent samples in the pixel that exactly overlap in *z* range. This is only useful if the pixel has previously been split at all sample starts and ends, and sorted by *Z*. Note that this may change the number of samples in the pixel.

void **merge_deep_pixels**(int64_t pixel, const *DeepData* &src, int srcpixel)
Merge the samples of `src`'s pixel into this *DeepData*'s pixel. Return `true` if ok, `false` if the operation could not be performed.

float **opaque_z**(int64_t pixel) const
Return the *z* depth at which the pixel reaches full opacity.

```
void occlusion_cull(int64_t pixel)
    Remove any samples hidden behind opaque samples.
```

2.8 Global Attributes

These helper functions are not part of any other OpenImageIO class, they just exist in the OpenImageIO namespace as general utilities. (See *Miscellaneous Utilities* for the corresponding Python bindings.)

```
bool OIIO::attribute(string_view name, TypeDesc type, const void *val)
```

`OIIO::attribute()` sets a global attribute (i.e., a property or option) of OpenImageIO. The name designates the name of the attribute, `type` describes the type of data, and `val` is a pointer to memory containing the new value for the attribute.

If the name is known, valid attribute that matches the type specified, the attribute will be set to the new value and `attribute()` will return `true`. If name is not recognized, or if the types do not match (e.g., `type` is `TypeFloat` but the named attribute is a string), the attribute will not be modified, and `attribute()` will return `false`.

The following are the recognized attributes:

- `string options`

This catch-all is simply a comma-separated list of `name=value` settings of named options, which will be parsed and individually set. For example,

```
OIIO::attribute ("options", "threads=4,log_times=1");
```

Note that if an option takes a string value that must itself contain a comma, it is permissible to enclose the value in either ‘single’ or “double” quotes.

- `int threads`

How many threads to use for operations that can be sped up by being multithreaded. (Examples: simultaneous format conversions of multiple scanlines read together, or many `ImageBufAlgo` operations.) The default is 0, meaning to use the full available hardware concurrency detected.

Situations where the main application logic is essentially single threaded (i.e., one top-level call into OIIO at a time) should leave this at the default value, or some reasonable number of cores, thus allowing lots of threads to fill the cores when OIIO has big tasks to complete. But situations where you have many threads at the application level, each of which is expected to be making separate OIIO calls simultaneously, should set this to 1, thus having each calling thread do its own work inside of OIIO rather than spawning new threads with a high overall “fan out.”

- `int exr_threads`

Sets the internal OpenEXR thread pool size. The default is to use as many threads as the amount of hardware concurrency detected. Note that this is separate from the OIIO “threads” attribute.

- `string font_searchpath`

Colon-separated (or semicolon-separated) list of directories to search if fonts are needed. (Such as for `ImageBufAlgo::render_text()`.)

- `int use_tbb`

If nonzero and TBB was found and support configured when OIIO was compiled, parallel processing within OIIO (including inside the `parallel.h` utilities) will try to use TBB by default where possible. If zero, they will try to use OIIO's native thread pool even if TBB is available.

- `string plugin_searchpath`

Colon-separated (or semicolon-separated) list of directories to search for dynamically-loaded format plugins.

- `int try_all_readers`

When nonzero (the default), a call to `ImageInput::create()` or `ImageInput::open()` that does not succeed in opening the file with the format reader implied by the file extension will try all available format readers to see if one of them can open the file. If this is zero, the only reader that will be tried is the one implied by the file extension.

- `int read_chunk`

When performing a `read_image()`, this is the number of scanlines it will attempt to read at a time (some formats are more efficient when reading and decoding multiple scanlines). The default is 256. The special value of 0 indicates that it should try to read the whole image if possible.

- `float[] missingcolor, string missingcolor`

This attribute may either be an array of float values, or a string containing a comma-separated list of the values. Setting this option globally is equivalent to always passing an `ImageInput` open-with-configuration hint "oiio:missingcolor" with the value.

When set, it gives some `ImageInput` readers the option of ignoring any *missing* tiles or scanlines in the file, and instead of treating the read failure of an individual tile as a full error, will interpret it as an intentionally missing tile and proceed by simply filling in the missing pixels with the color specified. If the first element is negative, it will use the absolute value, but draw alternating diagonal stripes of the color. For example,

```
float missing[4] = { -1.0, 0.0, 0.0, 0.0 }; // striped red
OIIO::attribute ("missingcolor", TypeDesc("float[4]"), &missing);
```

Note that only some file formats support files with missing tiles or scanlines, and this is only taken as a hint. Please see `chap-bundledplugins_` for details on which formats accept a "missingcolor" configuration hint.

- `int debug`

When nonzero, various debug messages may be printed. The default is 0 for release builds, 1 for DEBUG builds (values > 1 are for OIIO developers to print even more debugging information). This attribute but also may be overridden by the `OPENIMAGEIO_DEBUG` environment variable.

- `int tiff:half`

When nonzero, allows TIFF to write `half` pixel data. N.B. Most apps may not read these correctly, but OIIO will. That's why the default is not to support it.

- `int dds:bc5normal`

When nonzero, treats BC5/ATI2 format files as normal maps (loads as 3 channels, computes blue from red and green). Default is 0.

- `int openexr:core`

When nonzero, use the new "OpenEXR core C library" when available, for OpenEXR >= 3.1. This is experimental, and currently defaults to 0.

- `int limits:channels (1024)`

When nonzero, the maximum number of color channels in an image. Image files whose headers indicate they have more channels might be assumed to be corrupted or malicious files. In situations when more channels are expected to be encountered, the application should raise this limit. The default is 1024 channels.

- `int limits:image_size_MB (32768)`

When nonzero, the maximum expected size in MB of the uncompressed pixel data of a single 2D image. Images whose headers indicate that they are larger than this might be assumed to be corrupted or malicious files. The default is 32768 (32 GB of uncompressed pixel data; equivalent to 64k x 64k x 4 channel x half), or the total amount of total physical memory available to the running process, whichever is smaller. In situations when images larger than this are expected to be encountered, you should raise this limit. Setting the limit to 0 means having no limit.

- `int log_times (0)`

When the "log_times" attribute is nonzero, `ImageBufAlgo` functions are instrumented to record the number of times they were called and the total amount of time spent executing them. It can be overridden by environment variable `OPENIMAGEIO_LOG_TIMES`. The totals will be recorded and can be retrieved as a string by using `OIIO::getattribute("timing_report", ...)`. Additionally, if the value is 2 or more, the timing report will be printed to `stdout` upon application exit (not advised in contexts where it isn't ok to print to the terminal via `stdout`, such as GUI apps or libraries).

When enabled, there is a slight runtime performance cost due to checking the time at the start and end of each of those function calls, and the locking and recording of the data structure that holds the log information. When the `log_times` attribute is disabled, there is no additional performance cost.

- `oio:print_uncaught_errors (1)`

If nonzero, upon program exit, any error messages that would have been retrieved by a call to `OIIO::geterror()`, but never were, will be printed to `stdout`. While this may seem chaotic, we are presuming that any well-written library or application will proactively check error codes and retrieve errors, so this will never print anything upon exit. But for less sophisticated applications (or users), this is very useful for forcing display of error messages so that users can see relevant errors even if they never check them explicitly, thus self-diagnose their troubles before asking the project dev team for help. Advanced users who for some reason desire to neither retrieve errors themselves nor have them printed in this manner can disable the behavior by setting this attribute to 0.

- `imagebuf:print_uncaught_errors (1)`

If nonzero, an `ImageBuf` upon destruction will print any error messages that were never retrieved by its `geterror()` method. While this may seem chaotic, we are presuming that any well-written library or application will proactively check error codes and retrieve errors, so will never print anything upon destruction. But for less sophisticated applications (or users), this is very useful for forcing display of error messages so that users can see relevant errors even if they never check them explicitly, thus self-diagnose their troubles before asking the project dev team for help. Advanced users who for some reason desire to neither retrieve errors themselves nor have them printed in this manner can disable the behavior by setting this attribute to 0.

- `imagebuf:use_imagecache (0)`

If nonzero, an `ImageBuf` that references a file but is not given an *ImageCache* will read the image through the default *ImageCache*.

```
bool OIIO::attribute(string_view name, int val)
```

```
bool OIIO::attribute(string_view name, float val)
```

```
bool OIIO::attribute(string_view name, string_view val)
```

Shortcuts for setting an attribute to a single int, float, or string.

bool `OIIO::getattribute`(string_view name, *TypeDesc* type, void *val)

Get the named global attribute of OpenImageIO, store it in *val. Return `true` if found and it was compatible with the type specified, otherwise return `false` and do not modify the contents of *val. It is up to the caller to ensure that val points to the right kind and size of storage for the given type.

In addition to being able to retrieve all the attributes that are documented as settable by the `OIIO::attribute()` call, `getattribute()` can also retrieve the following read-only attributes:

- `string version`

The version designation of the OpenImageIO library, as a string.

- `string format_list`
- `string input_format_list`
- `string output_format_list`

A comma-separated list of all the names of, respectively, all supported image formats, all formats accepted as inputs, and all formats accepted as outputs.

- `string extension_list`

For each format, the format name, followed by a colon, followed by a comma-separated list of all extensions that are presumed to be used for that format. Semicolons separate the lists for formats. For example,

```
"tiff:tif;jpeg:jpg,jpeg;openexr:exr"
```

- `string library_list`

For each format that uses a dependent library, the format name, followed by a colon, followed by the name and version of the dependency. Semicolons separate the lists for formats. For example,

```
"tiff:LIBTIFF 4.0.4;gif:gif_lib 4.2.3;openexr:OpenEXR 2.2.0"
```

- `string font_list`
- `string font_file_list`
- `string font_dir_list`

A semicolon-separated list of, respectively, all the fonts that OpenImageIO can find, all the font files that OpenImageIO can find (with full paths), and all the directories that OpenImageIO will search for fonts. (Added in OpenImageIO 2.5)

- `string filter_list`

A semicolon-separated list of all built-in 2D filters. (Added in OpenImageIO 2.5.9)

- `int64_t IB_local_mem_current`
- `int64_t IB_local_mem_peak`

Current and peak size (in bytes) of how much memory was consumed by ImageBufs that owned their own allocated local pixel buffers. (Added in OpenImageIO 2.5.)

- `float IB_total_open_time`
- `float IB_total_image_read_time`

Total amount of time (in seconds) that ImageBufs spent opening (including reading header information) and reading pixel data from files that they opened and read themselves (that is, excluding I/O from IBs that were backed by ImageCach. (Added in OpenImageIO 2.5.)

- `string opencolorio_version`

Returns the version (such as “2.2.0”) of OpenColorIO that is used by OpenImageIO, or “0.0.0” if no OpenColorIO support has been enabled. (Added in OpenImageIO 2.4.6)

- `string hw:simd`

- `string build:simd` (read-only)

A comma-separated list of hardware CPU features for SIMD (and some other things). The “build:simd” attribute is similarly a list of which features this build of OIIO was compiled to support.

These were added in OpenImageIO 1.8. The “build:simd” attribute was added in OpenImageIO 2.5.8 as a preferred synonym for what previously was called “oiio:simd”, which is now deprecated.

- `string build:platform` (read-only)

The name of the OS and CPU architecture that OpenImageIO was built for (e.g., “Linux/x86_64”). (Added in OpenImageIO 2.5.8.)

- `string build:compiler` (read-only)

The name and version of the compiler used to build OIIO. (Added in OpenImageIO 2.5.8.)

- `string build:dependencies` (read-only)

List of library dependencies (where known) and versions, separated by semicolons. (Added in OpenImageIO 2.5.8.)

- `float resident_memory_used_MB`

This read-only attribute can be used for debugging purposes to report the approximate process memory used (resident) by the application, in MB.

- `string timing_report`

Retrieving this attribute returns the timing report generated by the `log_timing` attribute (if it was enabled). The report is sorted alphabetically and for each named instrumentation region, prints the number of times it executed, the total runtime, and the average per call, like this:

IBA::computePixelStats	2	2.69ms	(avg 1.34ms)
IBA::make_texture	1	74.05ms	(avg 74.05ms)
IBA::mul	8	2.42ms	(avg 0.30ms)
IBA::over	10	23.82ms	(avg 2.38ms)
IBA::resize	20	0.24s	(avg 12.18ms)
IBA::zero	8	0.66ms	(avg 0.08ms)

```
bool getattribute(string_view name, int &val)
```

```
bool getattribute(string_view name, float &val)
```

```
bool getattribute(string_view name, char **val)
```

```
bool getattribute(string_view name, std::string &val)
```

Specialized versions of `getattribute()` in which the data type is implied by the type of the argument (for single int, float, or string). Two string versions exist: one that retrieves it as a `std::string` and another that retrieves it as a `char *`. In all cases, the return value is `true` if the attribute is found and the requested data type conversion was legal.

EXAMPLES:

```
int threads;
OIIO::getattribute ("threads", &threads);
```

(continues on next page)

(continued from previous page)

```
std::string path;  
OIIO::getattribute ("plugin_searchpath", path);
```

int **get_int_attribute**(string_view name, int defaultvalue = 0)

float **get_float_attribute**(string_view name, float defaultvalue = 0)

string_view **get_string_attribute**(string_view name, string_view defaultvalue = "")

Specialized versions of `getattribute()` for common types, in which the data is returned directly, and a supplied default value is returned if the attribute was not found.

EXAMPLES:

```
int threads = OIIO::get_int_attribute ("threads", 0);  
string_view path = OIIO::get_string_attribute ("plugin_searchpath");
```

2.9 Miscellaneous Utilities

These helper functions are not part of any other OpenImageIO class, they just exist in the OIIO namespace as general utilities. (See *Miscellaneous Utilities* for the corresponding Python bindings.)

int OIIO::openimageio_version()

Returns a numeric value for the version of OpenImageIO, 10000 for each major version, 100 for each minor version, 1 for each patch. For example, OpenImageIO 1.2.3 would return a value of 10203. One example of how this is useful is for plugins to query the version to be sure they are linked against an adequate version of the library.

bool OIIO::has_error()

Is there a pending global error message waiting to be retrieved?

std::string OIIO::geterror(bool clear = true)

Returns any error string describing what went wrong if `ImageInput::create()` or `ImageOutput::create()` failed (since in such cases, the `ImageInput` or `ImageOutput` itself does not exist to have its own `geterror()` function called). This function returns the last error for this particular thread, and clear the pending error message unless `clear` is false; separate threads will not clobber each other's global error messages.

void OIIO::declare_imageio_format(const std::string &format_name, *ImageInput::Creator* input_creator, const char **input_extensions, *ImageOutput::Creator* output_creator, const char **output_extensions, const char *lib_version)

Register the input and output 'create' routines and list of file extensions for a particular format.

bool OIIO::is_imageio_format_name(string_view name)

Is `name` one of the known format names?

inline std::map<std::string, std::vector<std::string>> OIIO::get_extension_map()

Utility: Parse the "extension_list" attribute into a `std::map` string keys are the names of all the file formats OIIO knows how to read, and whose values are vectors of strings of the file extensions associated with the file format. (Added in OIIO 2.2.13.)

2.10 Startup and Shutdown

void `OIIO::shutdown()`

`OIIO::shutdown` prepares OpenImageIO for shutdown. Before exiting an application that utilizes OpenImageIO the `OIIO::shutdown` function must be called, which will perform shutdown of any running thread-pools. Failing to call `OIIO::shutdown` could lead to a sporadic dead-lock during application shutdown on certain platforms such as Windows.

2.11 Environment variables

There are a few special environment variables that can be used to control OpenImageIO at times that it is not convenient to set options individually from inside the source code.

OPENIMAGEIO_FONTS

A searchpath for finding fonts (for example, when using by `ImageBufAlgo::render_text` or `oiio tool --text`). This may contain a list of directories separated by “:” or “;”.

OPENIMAGEIO_OPTIONS

Allows you to seed the global OpenImageIO-wide options.

The value of the environment variable should be a comma-separated list of *name=value* settings. If a value is a string that itself needs to contain commas, it may be enclosed in single or double quotes.

Upon startup, the contents of this environment variable will be passed to a call to:

```
OIIO::attribute ("options", value);
```

OPENIMAGEIO_IMAGECACHE_OPTIONS

Allows you to seed the options for any ImageCache created.

The value of the environment variable should be a comma-separated list of *name=value* settings. If a value is a string that itself needs to contain commas, it may be enclosed in single or double quotes.

Upon creation of any ImageCache, the contents of this environment variable will be passed to a call to:

```
imagecache->attribute ("options", value);
```

OPENIMAGEIO_PLUGIN_PATH

A colon-separated list of directories to search for OpenImageIO plugins (dynamically loadable libraries that implement image format readers and writers).

This is a new name beginning with OpenImageIO 2.6.3. The old name `OIIO_LIBRARY_PATH` is still supported, but deprecated.

OPENIMAGEIO_TEXTURE_OPTIONS

Allows you to seed the options for any TextureSystem created.

The value of the environment variable should be a comma-separated list of **name=value** settings. If a value is a string that itself needs to contain commas, it may be enclosed in single or double quotes.

Upon creation of any `TextureSystem`, the contents of this environment variable will be passed to a call to:

```
texturesys->attribute ("options", value);
```

OPENIMAGEIO_THREADS, CUE_THREADS

Either of these sets the default number of threads that OpenImageIO will use for its thread pool. If both are set, `OPENIMAGEIO_THREADS` will take precedence. If neither is set, the default will be 0, which means to use as many threads as there are physical cores on the machine.

OPENIMAGEIO_METADATA_HISTORY

If set to a nonzero integer value, `oiiotool` and `maketx` will by default write the command line into the `ImageHistory` and `Software` metadata fields of any images it outputs. The default if this is not set is to only write the name and version of the software and an indecipherable hash of the command line, but not the full human-readable command line. (This was added in OpenImageIO 2.5.11.)

IMAGEOUTPUT: WRITING IMAGES

3.1 Image Output Made Simple

Here is the simplest sequence required to write the pixels of a 2D image to a file:

C++

```
#include <OpenImageIO/imageio.h>
using namespace OIIO;

void simple_write()
{
    const char* filename = "simple.tif";
    const int xres = 320, yres = 240, channels = 3;
    unsigned char pixels[xres * yres * channels] = { 0 };

    std::unique_ptr<ImageOutput> out = ImageOutput::create(filename);
    if (!out)
        return; // error
    ImageSpec spec(xres, yres, channels, TypeDesc::UINT8);
    out->open(filename, spec);
    out->write_image(TypeDesc::UINT8, pixels);
    out->close();
}
```

Python

```
import OpenImageIO as oiio
import numpy as np

def simple_write() :
    filename = "simple.tif"
    xres = 320
    yres = 240
    channels = 3 # RGB
    pixels = np.zeros((yres, xres, channels), dtype=np.uint8)

    out = oiio.ImageOutput.create (filename)
    if out:
        spec = oiio.ImageSpec(xres, yres, channels, 'uint8')
        out.open (filename, spec)
```

(continues on next page)

(continued from previous page)

```
out.write_image (pixels)
out.close ()
```

This little bit of code does a surprising amount of useful work:

- Search for an ImageIO plugin that is capable of writing the file `foo.jpg`), deducing the format from the file extension. When it finds such a plugin, it creates a subclass instance of `ImageOutput` that writes the right kind of file format.

C++

```
std::unique_ptr<ImageOutput> out = ImageOutput::create (filename);
```

Python

```
out = ImageOutput.create (filename)
```

- Open the file, write the correct headers, and in all other important ways prepare a file with the given dimensions (320 x 240), number of color channels (3), and data format (unsigned 8-bit integer).

C++

```
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);
out->open (filename, spec);
```

Python

```
spec = ImageSpec (xres, yres, channels, 'uint8')
out.open (filename, spec)
```

- Write the entire image, hiding all details of the encoding of image data in the file, whether the file is scanline- or tile-based, or what is the native format of data in the file (in this case, our in-memory data is unsigned 8-bit and we've requested the same format for disk storage, but if they had been different, `write_image()` would do all the conversions for us).

C++

```
out->write_image (TypeDesc::UINT8, &pixels);
```

Python

```
out.write_image (pixels)
```

- Close the file.

C++

```
out->close ();
```

Python

```
out.close ()
```

What happens when the file format doesn't support the spec?

The `open()` call will fail (returning an empty pointer and set an appropriate error message) if the output format cannot accommodate what is requested by the `ImageSpec`. This includes:

- Dimensions (width, height, or number of channels) exceeding the limits supported by the file format.¹
- Volumetric (depth > 1) if the format does not support volumetric data.
- Tile size >1 if the format does not support tiles.
- Multiple subimages or MIP levels if not supported by the format.

However, several other mismatches between requested ImageSpec and file format capabilities will be silently ignored, allowing `open()` to succeed:

- If the pixel data format is not supported (for example, a request for `half` pixels when writing a JPEG/JFIF file), the format writer may substitute another data format (generally, whichever commonly-used data format supported by the file type will result in the least reduction of precision or range).
- If the ImageSpec requests different per-channel data formats, but the format supports only a single format for all channels, it may just choose the most precise format requested and use it for all channels.
- If the file format does not support arbitrarily-named channels, the channel names may be lost when saving the file.
- Any other metadata in the ImageSpec may be summarily dropped if not supported by the file format.

3.2 Advanced Image Output

Let's walk through many of the most common things you might want to do, but that are more complex than the simple example above.

3.2.1 Writing individual scanlines, tiles, and rectangles

The simple example of Section *Image Output Made Simple* wrote an entire image with one call. But sometimes you are generating output a little at a time and do not wish to retain the entire image in memory until it is time to write the file. OpenImageIO allows you to write images one scanline at a time, one tile at a time, or by individual rectangles.

Writing individual scanlines

Individual scanlines may be written using the `write_scanline()` API call:

C++

```
unsigned char scanline[xres * channels] = { 0 };
out->open (filename, spec);
int z = 0;    // Always zero for 2D images
for (int y = 0; y < yres; ++y) {
    // ... generate data in scanline[0..xres*channels-1] ...
    out->write_scanline (y, z, TypeDesc::UINT8, scanline);
}
out->close();
```

Python

¹ One exception to the rule about number of channels is that a file format that supports only RGB, but not alpha, is permitted to silently drop the alpha channel without considering that to be an error.

```
z = 0    # Always zero for 2D images
out.open (filename, spec)
for y in range(yres) :
    # Generate pixel array for one scanline.
    # As an example, we are just making a zero-filled scanline
    scanline = np.zeros((xres, channels), dtype=np.uint8)
    out.write_scanline (y, z, scanline)
out.close ()
```

The first two arguments to `write_scanline()` specify which scanline is being written by its vertical (*y*) scanline number (beginning with 0) and, for volume images, its slice (*z*) number (the slice number should be 0 for 2D non-volume images). This is followed by a `TypeDesc` describing the data you are supplying, and a pointer to the pixel data itself. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section [Data Strides](#)).

All `ImageOutput` implementations will accept scanlines in strict order (starting with scanline 0, then 1, up to `yres-1`, without skipping any). See Section [Random access and repeated transmission of pixels](#) for details on out-of-order or repeated scanlines.

The full description of the `write_scanline()` function may be found in Section [ImageOutput Class Reference](#).

Writing individual tiles

Not all image formats (and therefore not all `ImageOutput` implementations) support tiled images. If the format does not support tiles, then `write_tile()` will fail. An application using `OpenImageIO` should gracefully handle the case that tiled output is not available for the chosen format.

Once you `create()` an `ImageOutput`, you can ask if it is capable of writing a tiled image by using the `supports("tiles")` query:

C++

```
std::unique_ptr<ImageOutput> out = ImageOutput::create (filename);
if (! out->supports ("tiles")) {
    // Tiles are not supported
}
```

Python

```
out = ImageOutput.create (filename)
if not out.supports ("tiles") :
    # Tiles are not supported
```

Assuming that the `ImageOutput` supports tiled images, you need to specifically request a tiled image when you `open()` the file. This is done by setting the tile size in the `ImageSpec` passed to `open()`. If the tile dimensions are not set, they will default to zero, which indicates that scanline output should be used rather than tiled output.

C++

```
int tileSize = 64;
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);
spec.tile_width = tileSize;
spec.tile_height = tileSize;
out->open (filename, spec);
```

Python

```

tilesize = 64
spec = ImageSpec (xres, yres, channels, 'uint8')
spec.tile_width = tilesize
spec.tile_height = tilesize
out.open (filename, spec)

```

In this example, we have used square tiles (the same number of pixels horizontally and vertically), but this is not a requirement of OpenImageIO. However, it is possible that some image formats may only support square tiles, or only certain tile sizes (such as restricting tile sizes to powers of two). Such restrictions should be documented by each individual plugin.

C++

```

unsigned char tile[tilesize*tilesize*channels];
int z = 0;    // Always zero for 2D images
for (int y = 0; y < yres; y += tilesize) {
    for (int x = 0; x < xres; x += tilesize) {
        ... generate data in tile[] ..
        out->write_tile (x, y, z, TypeDesc::UINT8, tile);
    }
}
out->close ();

```

Python

```

z = 0 # Always zero for 2D images
for y in range(0, yres, tilesize):
    for x in range(0, xres, tilesize):
        # ... generate data in tile[][][] ..
        out.write_tile (x, y, z, tile)
out.close ()

```

The first three arguments to `write_tile()` specify which tile is being written by the pixel coordinates of any pixel contained in the tile: `x` (column), `y` (scanline), and `z` (slice, which should always be 0 for 2D non-volume images). This is followed by a `TypeDesc` describing the data you are supplying, and a pointer to the tile's pixel data itself, which should be ordered by increasing slice, increasing scanline within each slice, and increasing column within each scanline. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section [Data Strides](#)).

All `ImageOutput` implementations that support tiles will accept tiles in strict order of increasing `y` rows, and within each row, increasing `x` column, without missing any tiles. See

The full description of the `write_tile()` function may be found in Section [ImageOutput Class Reference](#).

Writing arbitrary rectangles

Some `ImageOutput` implementations — such as those implementing an interactive image display, but probably not any that are outputting directly to a file — may allow you to send arbitrary rectangular pixel regions. Once you `create()` an `ImageOutput`, you can ask if it is capable of accepting arbitrary rectangles by using the `supports("rectangles")` query:

C++

```
std::unique_ptr<ImageOutput> out = ImageOutput::create (filename);
if (! out->supports ("rectangles")) {
    // Rectangles are not supported
}
```

Python

```
out = ImageOutput.create (filename)
if not out.supports ("rectangles") :
    # Rectangles are not supported
```

If rectangular regions are supported, they may be sent using the `write_rectangle()` API call:

C++

```
unsigned int rect[...];
// ... generate data in rect[] ...
out->write_rectangle (xbegin, xend, ybegin, yend, zbegin, zend,
                    TypeDesc::UINT8, rect);
```

Python

```
# generate data in rect[] ...
out.write_rectangle (xbegin, xend, ybegin, yend, zbegin, zend, rect)
```

The first six arguments to `write_rectangle()` specify the region of pixels that is being transmitted by supplying the minimum and one-past-maximum pixel indices in *x* (column), *y* (scanline), and *z* (slice, always 0 for 2D non-volume images).

Note: OpenImageIO nearly always follows the C++ STL convention of specifying ranges as the half-open interval `[begin,end)` specifying the sequence `begin, begin+1, ..., end-1` (but the sequence does not contain the end value itself).

The total number of pixels being transmitted is therefore:

```
(xend - xbegin) * (yend - ybegin) * (zend - zbegin)
```

This is followed by a `TypeDesc` describing the data you are supplying, and a pointer to the rectangle's pixel data itself, which should be ordered by increasing slice, increasing scanline within each slice, and increasing column within each scanline. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section [Data Strides](#)).

3.2.2 Converting pixel data types

The code examples of the previous sections all assumed that your internal pixel data is stored as unsigned 8-bit integers (i.e., 0-255 range). But OpenImageIO is significantly more flexible.

You may request that the output image pixels be stored in any of several data types. This is done by setting the `format` field of the `ImageSpec` prior to calling `open`. You can do this upon construction of the `ImageSpec`, as in the following example that requests a spec that stores pixel values as 16-bit unsigned integers:

```
ImageSpec spec (xres, yres, channels, TypeDesc::UINT16);
```

Or, for an `ImageSpec` that has already been constructed, you may reset its format using the `set_format()` method.

C++

```
ImageSpec spec(...);
spec.set_format(TypeDesc::UINT16);
```

Python

```
spec = ImageSpec(...)
spec.set_format("uint16")
```

Note that resetting the pixel data type must be done *before* passing the spec to `open()`, or it will have no effect on the file.

Individual file formats, and therefore `ImageOutput` implementations, may only support a subset of the pixel data types understood by the OpenImageIO library. Each `ImageOutput` plugin implementation should document which data formats it supports. An individual `ImageOutput` implementation is expected to always succeed, but if the file format does not support the requested pixel data type, it is expected to choose a data type that is supported, usually the data type that best preserves the precision and range of the originally-requested data type.

The conversion from floating-point formats to integer formats (or from higher to lower integer, which is done by first converting to float) is always done by rescaling the value so that 0.0 maps to integer 0 and 1.0 to the maximum value representable by the integer type, then rounded to an integer value for final output. Here is the code that implements this transformation (T is the final output integer type):

```
float value = quant_max * input;
T output = (T) clamp((int)(value + 0.5), quant_min, quant_max);
```

Quantization limits for each integer type is as follows:

Data Format	min	max
UINT8	0	255
INT8	-128	127
UINT16	0	65535
INT16	-32768	32767
UINT	0	4294967295
INT	-2147483648	2147483647

Note that the default is to use the entire positive range of each integer type to represent the floating-point (0.0 - 1.0) range. Floating-point types do not attempt to remap values, and do not clamp (except to their full floating-point range).

It is not required that the pixel data passed to `write_image()`, `write_scanline()`, `write_tile()`, or `write_rectangle()` actually be in the same data type as that requested as the native pixel data type of the file. You can fully mix and match data you pass to the various “write” routines and OpenImageIO will automatically convert from the internal format to the native file format. For example, the following code will open a TIFF file that stores pixel data as 16-bit unsigned integers (values ranging from 0 to 65535), compute internal pixel values as floating-point values, with `write_image()` performing the conversion automatically:

C++

```
std::unique_ptr<ImageOutput> out = ImageOutput::create("myfile.tif");
ImageSpec spec(xres, yres, channels, TypeDesc::UINT16);
out->open(filename, spec);
...
float pixels[xres*yres*channels];
```

(continues on next page)

(continued from previous page)

```
...
out->write_image (TypeDesc::FLOAT, pixels);
```

Python

```
out = ImageOutput.create ("myfile.tif")
spec = ImageSpec (xres, yres, channels, "uint16")
out.open (filename, spec)
...
pixels = (...)
...
out.write_image (pixels)
```

Note that `write_scanline()`, `write_tile()`, and `write_rectangle()` have a parameter that works in a corresponding manner.

3.2.3 Data Strides

In the preceding examples, we have assumed that the block of data being passed to the “write” functions are *contiguous*, that is:

- each pixel in memory consists of a number of data values equal to the declared number of channels that are being written to the file;
- successive column pixels within a row directly follow each other in memory, with the first channel of pixel x immediately following last channel of pixel $x-1$ of the same row;
- for whole images, tiles or rectangles, the data for each row immediately follows the previous one in memory (the first pixel of row y immediately follows the last column of row $y-1$);
- for 3D volumetric images, the first pixel of slice z immediately follows the last pixel of slice $z-1$.

Please note that this implies that data passed to `write_tile()` be contiguous in the shape of a single tile (not just an offset into a whole image worth of pixels), and that data passed to `write_rectangle()` be contiguous in the dimensions of the rectangle.

The `write_scanline()` function takes an optional `xstride` argument, and the `write_image()`, `write_tile()`, and `write_rectangle()` functions take optional `xstride`, `ystride`, and `zstride` values that describe the distance, in *bytes*, between successive pixel columns, rows, and slices, respectively, of the data you are passing. For any of these values that are not supplied, or are given as the special constant `AutoStride`, contiguity will be assumed.

By passing different stride values, you can achieve some surprisingly flexible functionality. A few representative examples follow:

- Flip an image vertically upon writing, by using negative y stride:

```
unsigned char pixels[xres*yres*channels];
int scanlinesize = xres * channels * sizeof(pixels[0]);
...
out->write_image (TypeDesc::UINT8,
                 (char *)pixels+(yres-1)*scanlinesize, // offset to last
                 AutoStride,                          // default x stride
                 -scanlinesize,                        // special y stride
                 AutoStride);                          // default z stride
```

- Write a tile that is embedded within a whole image of pixel data, rather than having a one-tile-only memory layout:

```
unsigned char pixels[xres*yres*channels];
int pixelsize = channels * sizeof(pixels[0]);
int scanlinesize = xres * pixelsize;
...
out->write_tile (x, y, 0, TypeDesc::UINT8,
                (char *)pixels + y*scanlinesize + x*pixelsize,
                pixelsize,
                scanlinesize);
```

- Write only a subset of channels to disk. In this example, our internal data layout consists of 4 channels, but we write just channel 3 to disk as a one-channel image:

```
// In-memory representation is 4 channel
const int xres = 640, yres = 480;
const int channels = 4; // RGBA
const int channelsize = sizeof(unsigned char);
unsigned char pixels[xres*yres*channels];

// File representation is 1 channel
std::unique_ptr<ImageOutput> out = ImageOutput::create (filename);
ImageSpec spec (xres, yres, 1, TypeDesc::UINT8);
out->open (filename, spec);

// Use strides to write out a one-channel "slice" of the image
out->write_image (TypeDesc::UINT8,
                (char *)pixels+3*channelsize, // offset to chan 3
                channels*channelsize,        // 4 channel x stride
                AutoStride,                   // default y stride
                AutoStride);                 // default z stride
...
```

Please consult Section *ImageOutput Class Reference* for detailed descriptions of the stride parameters to each “write” function.

3.2.4 Writing a crop window or overscan region

The ImageSpec fields *width*, *height*, and *depth* describe the dimensions of the actual pixel data.

At times, it may be useful to also describe an abstract *full* or *display* image window, whose position and size may not correspond exactly to the data pixels. For example, a pixel data window that is a subset of the full display window might indicate a *crop* window; a pixel data window that is a superset of the full display window might indicate *overscan* regions (pixels defined outside the eventual viewport).

The ImageSpec fields *full_width*, *full_height*, and *full_depth* describe the dimensions of the full display window, and *full_x*, *full_y*, *full_z* describe its origin (upper left corner). The fields *x*, *y*, *z* describe the origin (upper left corner) of the pixel data.

These fields collectively describe an abstract full display image ranging from [*full_x* ... *full_x*+*full_width*-1] horizontally, [*full_y* ... *full_y*+*full_height*-1] vertically, and [*full_z* ... *full_z*+*full_depth*-1] in depth (if it is a 3D volume), and actual pixel data over the pixel coordinate range [*x* ... *x*+*width*-1] horizontally, [*y* ... *y*+*height*-1] vertically, and [*z* ... *z*+*depth*-1] in depth (if it is a volume).

Not all image file formats have a way to describe display windows. An ImageOutput implementation that cannot express display windows will always write out the width * height pixel data, may upon writing lose information about offsets or crop windows.

Here is a code example that opens an image file that will contain a 32x32 pixel crop window within an abstract 640 x 480 full size image. Notice that the pixel indices (column, scanline, slice) passed to the “write” functions are the coordinates relative to the full image, not relative to the crop widow, but the data pointer passed to the “write” functions should point to the beginning of the actual pixel data being passed (not the the hypothetical start of the full data, if it was all present).

C++

```
int fullwidth = 640, fulllength = 480; // Full display image size
int cropwidth = 16, croplength = 16;  // Crop window size
int xorigin = 32, yorigin = 128;      // Crop window position
unsigned char pixels [cropwidth * croplength * channels]; // Crop size
...
std::unique_ptr<ImageOutput> out = ImageOutput::create(filename);
ImageSpec spec(cropwidth, croplength, channels, TypeDesc::UINT8);
spec.full_x = 0;
spec.full_y = 0;
spec.full_width = fullwidth;
spec.full_length = fulllength;
spec.x = xorigin;
spec.y = yorigin;
out->open(filename, spec);
...
int z = 0; // Always zero for 2D images
for (int y = yorigin; y < yorigin+croplength; ++y) {
    out->write_scanline(y, z, TypeDesc::UINT8,
                       &pixels[(y-yorigin)*cropwidth*channels]);
}
out->close();
```

Python

```
fullwidth = 640
fulllength = 480 # Full display image size
cropwidth = 16
croplength = 16 # Crop window size
xorigin = 32
yorigin = 128 # Crop window position
pixels = numpy.zeros((croplength, cropwidth, channels), dtype="uint8")
...
spec = ImageSpec(cropwidth, croplength, channels, "uint8")
spec.full_x = 0
spec.full_y = 0
spec.full_width = fullwidth
spec.full_length = fulllength
spec.x = xorigin
spec.y = yorigin
out = ImageOutput.open(filename, spec)
...
z = 0 # Always zero for 2D images
for y in range(yorigin, yorigin+croplength) :
```

(continues on next page)

(continued from previous page)

```

    out.write_scanline (y, z, TypeDesc::UINT8,
                        pixels[y-origin:y-origin+1])
out.close()

```

3.2.5 Writing metadata

The `ImageSpec` passed to `open()` can specify all the common required properties that describe an image: data format, dimensions, number of channels, tiling. However, there may be a variety of additional *metadata* that should be carried along with the image or saved in the file.

Note: *Metadata* refers to data about data, in this case, data about the image that goes beyond the pixel values and description thereof.

The remainder of this section explains how to store additional metadata in the `ImageSpec`. It is up to the `ImageOutput` to store these in the file, if indeed the file format is able to accept the data. Individual `ImageOutput` implementations should document which metadata they respect.

Channel names

In addition to specifying the number of color channels, it is also possible to name those channels. Only a few `ImageOutput` implementations have a way of saving this in the file, but some do, so you may as well do it if you have information about what the channels represent.

By convention, channel names for red, green, blue, and alpha (or a main image) should be named "R", "G", "B", and "A", respectively. Beyond this guideline, however, you can use any names you want.

The `ImageSpec` has a vector of strings called `channelnames`. Upon construction, it starts out with reasonable default values. If you use it at all, you should make sure that it contains the same number of strings as the number of color channels in your image. Here is an example:

C++

```

int channels = 3;
ImageSpec spec (width, length, channels, TypeDesc::UINT8);
spec.channelnames.assign ({ "R", "G", "B" });

```

Python

```

channels = 3
spec = ImageSpec(width, length, channels, "uint8")
spec.channelnames = ("R", "G", "B")

```

Here is another example in which custom channel names are used to label the channels in an 8-channel image containing beauty pass RGB, per-channel opacity, and texture s,t coordinates for each pixel.

C++

```

int channels = 8;
ImageSpec spec (width, length, channels, TypeDesc::UINT8);
spec.channelnames.clear ();
spec.channelnames.assign ({ "R", "G", "B", "opacityR", "opacityG",
                           "opacityB", "texture_s", "texture_t" });

```

Python

```
channels = 8
spec = ImageSpec(width, length, channels, "uint8")
spec.channelnames = ("R", "G", "B", "opacityR", "opacityG", "opacityB",
                    "texture_s", "texture_t")
```

The main advantage to naming color channels is that if you are saving to a file format that supports channel names, then any application that uses OpenImageIO to read the image back has the option to retain those names and use them for helpful purposes. For example, the `iv` image viewer will display the channel names when viewing individual channels or displaying numeric pixel values in “pixel view” mode.

Specially-designated channels

The `ImageSpec` contains two fields, `alpha_channel` and `z_channel`, which can be used to designate which channel indices are used for alpha and *z* depth, if any. Upon construction, these are both set to `-1`, indicating that it is not known which channels are alpha or depth. Here is an example of setting up a 5-channel output that represents RGBAZ:

C++

```
int channels = 5;
ImageSpec spec (width, length, channels, format);
spec.channelnames.assign({ "R", "G", "B", "A", "Z" });
spec.alpha_channel = 3;
spec.z_channel = 4;
```

Python

```
channels = 5
spec = ImageSpec(width, length, channels, "uint8")
spec.channelnames = ("R", "G", "B", "A", "Z")
spec.alpha_channel = 3
spec.z_channel = 4
```

There are advantages to designating the alpha and depth channels in this manner: Some file formats may require that these channels be stored in a particular order, with a particular precision, or the `ImageOutput` may in some other way need to know about these special channels.

Arbitrary metadata

For all other metadata that you wish to save in the file, you can attach the data to the `ImageSpec` using the `attribute()` methods. These come in polymorphic varieties that allow you to attach an attribute name and a value consisting of a single `int`, `unsigned int`, `float`, `char*`, or `std::string`, as shown in the following examples:

C++

```
ImageSpec spec (...);

int i = 1;
spec.attribute ("Orientation", i);

float f = 72.0f;
spec.attribute ("dotsize", f);
```

(continues on next page)

(continued from previous page)

```
std::string s = "Fabulous image writer 1.0";
spec.attribute ("Software", s);
```

Python

```
spec = ImageSpec(...)

int i = 1
spec.attribute ("Orientation", i)

x = 72.0
spec.attribute ("dotsize", f)

s = "Fabulous image writer 1.0"
spec.attribute ("Software", s)
```

These are convenience routines for metadata that consist of a single value of one of these common types. For other data types, or more complex arrangements, you can use the more general form of `attribute()`, which takes arguments giving the name, type (as a `TypeDesc`), number of values (1 for a single value, >1 for an array), and then a pointer to the data values. For example,

C++

```
ImageSpec spec (...);

// Attach a 4x4 matrix to describe the camera coordinates
float mymatrix[16] = { ... };
spec.attribute ("worldtocamera", TypeMatrix, &mymatrix);

// Attach an array of two floats giving the CIE neutral color
float neutral[2] = { 0.3127, 0.329 };
spec.attribute ("adoptedNeutral", TypeDesc(TypeDesc::FLOAT, 2), &neutral);
```

Python

```
spec = ImageSpec(...)

# Attach a 4x4 matrix to describe the camera coordinates
mymatrix = (1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1)
spec.attribute ("worldtocamera", "matrix", mymatrix)

# Attach an array of two floats giving the CIE neutral color
neutral = (0.3127, 0.329)
spec.attribute ("adoptedNeutral", "float[2]", neutral)
```

Additionally, the `["key"]` notation may be used to set metadata in the spec as if it were an associative array or dictionary:

C++

```
// spec["key"] = value sets the value of the metadata, using
// the type of value as a guide for the type of the metadata.
spec["Orientation"] = 1; // int
spec["PixelAspectRatio"] = 1.0f; // float
```

(continues on next page)

(continued from previous page)

```
spec["ImageDescription"] = "selfie"; // string
spec["worldtocamera"] = Imath::M44f(...) // matrix
```

Python

```
// spec["key"] = value sets the value of the metadata, just
// like a Python dict.
spec["Orientation"] = 1
spec["PixelAspectRatio"] = 1.0
spec["ImageDescription"] = "selfie"
spec["worldtocamera"] = (1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1)
```

In general, most image file formats (and therefore most `ImageOutput` implementations) are aware of only a small number of name/value pairs that they predefine and will recognize. Some file formats (OpenEXR, notably) do accept arbitrary user data and save it in the image file. If an `ImageOutput` does not recognize your metadata and does not support arbitrary metadata, that metadatum will be silently ignored and will not be saved with the file.

Each individual `ImageOutput` implementation should document the names, types, and meanings of all metadata attributes that they understand.

Color space hints

We certainly hope that you are using only modern file formats that support high precision and extended range pixels (such as OpenEXR) and keeping all your images in a linear color space. But you may have to work with file formats that dictate the use of nonlinear color values. This is prevalent in formats that store pixels only as 8-bit values, since 256 values are not enough to linearly represent colors without banding artifacts in the dim values.

Since this can (and probably will) happen, we have a convention for explaining what color space your image pixels are in. Each individual `ImageOutput` should document how it uses this (or not).

The `ImageSpec::extra_attribs` field should store metadata that reveals the color space of the pixels you are sending the `ImageOutput` (see Section [Color information metadata](#) for explanations of particular values).

The color space hints only describe color channels. You should always pass alpha, depth, or other non-color channels with linear values.

Here is a simple example of setting up the `ImageSpec` when you know that the pixel values you are writing are in your default linear scene-referred color space:

C++

```
ImageSpec spec (width, length, channels, format);
spec.attribute ("oiio:ColorSpace", "scene_linear");
```

Python

```
spec = ImageSpec(width, length, channels, format)
spec.attribute ("oiio:ColorSpace", "scene_linear")
```

If a particular `ImageOutput` implementation is required (by the rules of the file format it writes) to have pixels in a fixed color space, then it should try to convert the color values of your image to the right color space if it is not already in that space. For example, JPEG images must be in sRGB space, so if you declare your pixels to be "scene_linear", the JPEG `ImageOutput` will convert to sRGB.

If you leave the "oiio:ColorSpace" unset, the values will not be transformed, since the plugin can't be sure that it's not in the correct space to begin with.

3.2.6 Random access and repeated transmission of pixels

All `ImageOutput` implementations that support scanlines and tiles should write pixels in strict order of increasing z slice, increasing y scanlines/rows within each slice, and increasing x column within each row. It is generally not safe to skip scanlines or tiles, or transmit them out of order, unless the plugin specifically advertises that it supports random access or rewrites, which may be queried using:

C++

```
auto out = ImageOutput::create(filename);
if (out->supports("random_access"))
    ...
```

Python

```
out = ImageOutput.create(filename)
if out.supports("random_access") :
    ...
```

Similarly, you should assume the plugin will not correctly handle repeated transmissions of a scanline or tile that has already been sent, unless it advertises that it supports rewrites, which may be queried using:

C++

```
if (out->supports("rewrite"))
    ...
```

Python

```
if out.supports("rewrite") :
    ...
```

3.2.7 Multi-image files

Some image file formats support storing multiple images within a single file. Given a created `ImageOutput`, you can query whether multiple images may be stored in the file:

C++

```
auto out = ImageOutput::create(filename);
if (out->supports("multiimage"))
    ...
```

Python

```
out = ImageOutput.create(filename)
if out->supports("multiimage") :
    ...
```

Some image formats allow you to do the initial `open()` call without declaring the specifics of the subimages, and simply append subimages as you go. You can detect this by checking

C++

```
if (out->supports("appendsubimage"))
    ...
```

Python

```
if out.supports("appendsubimage") :  
    ...
```

In this case, all you have to do is, after writing all the pixels of one image but before calling `close()`, call `open()` again for the next subimage and pass `AppendSubimage` as the value for the *mode* argument (see Section [ImageOutput Class Reference](#) for the full technical description of the arguments to `open()`). The `close()` routine is called just once, after all subimages are completed. Here is an example:

C++

```
const char *filename = "foo.tif";  
int nsubimages;      // assume this is set  
ImageSpec specs[];   // assume these are set for each subimage  
unsigned char *pixels[]; // assume a buffer for each subimage  
  
// Create the ImageOutput  
auto out = ImageOutput::create (filename);  
  
// Be sure we can support subimages  
if (subimages > 1 && (! out->supports("multiimage") ||  
                     ! out->supports("appendsubimage"))) {  
    std::cerr << "Does not support appending of subimages\n";  
    return;  
}  
  
// Use Create mode for the first level.  
ImageOutput::OpenMode appendmode = ImageOutput::Create;  
  
// Write the individual subimages  
for (int s = 0; s < nsubimages; ++s) {  
    out->open (filename, specs[s], appendmode);  
    out->write_image (TypeDesc::UINT8, pixels[s]);  
    // Use AppendSubimage mode for subsequent levels  
    appendmode = ImageOutput::AppendSubimage;  
}  
out->close ();
```

Python

```
filename = "foo.tif"  
nsubimages = ...      # assume this is set  
ImageSpec specs = (...) # assume these are set for each subimage  
pixels = (...)        # assume a buffer for each subimage  
  
# Create the ImageOutput  
out = ImageOutput.create(filename)  
  
# Be sure we can support subimages  
if subimages > 1 and (not out->supports("multiimage") or  
                     not out->supports("appendsubimage")) :  
    print("Does not support appending of subimages")  
    return
```

(continues on next page)

(continued from previous page)

```

# Use Create mode for the first level.
appendmode = "Create"

# Write the individual subimages
for s in range(nsubimages) :
    out.open (filename, specs[s], appendmode)
    out.write_image (pixels[s])
    # Use AppendSubimage mode for subsequent levels
    appendmode = "AppendSubimage"
out.close ()

```

On the other hand, if `out->supports("appendsubimage")` returns false, then you must use a different `open()` variety that allows you to declare the number of subimages and their specifications up front.

Below is an example of how to write a multi-subimage file, assuming that you know all the image specifications ahead of time. This should be safe for any file format that supports multiple subimages, regardless of whether it supports appending, and thus is the preferred method for writing subimages, assuming that you are able to know the number and specification of the subimages at the time you first open the file.

C++

```

const char *filename = "foo.tif";
int nsubimages;      // assume this is set
ImageSpec specs[];   // assume these are set for each subimage
unsigned char *pixels[]; // assume a buffer for each subimage

// Create the ImageOutput
auto out = ImageOutput::create (filename);

// Be sure we can support subimages
if (subimages > 1 && (! out->supports("multiimage") ||
    ! out->supports("appendsubimage")))) {
    std::cerr << "Does not support appending of subimages\n";
    return;
}

// Open and declare all subimages
out->open (filename, nsubimages, specs);

// Write the individual subimages
for (int s = 0; s < nsubimages; ++s) {
    if (s > 0) // Not needed for the first, which is already open
        out->open (filename, specs[s], ImageInput::AppendSubimage);
    out->write_image (TypeDesc::UINT8, pixels[s]);
}
out->close ();

```

Python

```

filename = "foo.tif"
nsubimages = ...      # assume this is set
ImageSpec specs = (...) # assume these are set for each subimage

```

(continues on next page)

(continued from previous page)

```

pixels = (...)          # assume a buffer for each subimage

# Create the ImageOutput
out = ImageOutput.create(filename)

# Be sure we can support subimages
if subimages > 1 and (not out->supports("multiimage") or
                     not out->supports("appendsubimage")) :
    print("Does not support appending of subimages")
    return

# Open and declare all subimages
out.open (filename, nsubimages, specs)

# Write the individual subimages
for s in range(nsubimages) :
    if s > 0 :
        out.open (filename, specs[s], "AppendSubimage")
        out.write_image (pixels[s])
out.close ()

```

In both of these examples, we have used `write_image()`, but of course `write_scanline()`, `write_tile()`, and `write_rectangle()` work as you would expect, on the current subimage.

3.2.8 MIP-maps

Some image file formats support multiple copies of an image at successively lower resolutions (MIP-map levels, or an “image pyramid”). Given a created `ImageOutput`, you can query whether MIP-maps may be stored in the file:

C++

```

auto out = ImageOutput::create (filename);
if (out->supports ("mipmap"))
    ...

```

Python

```

out = ImageOutput.create(filename)
if out.supports("mipmap") :
    ...

```

If you are working with an `ImageOutput` that supports MIP-map levels, it is easy to write these levels. After writing all the pixels of one MIP-map level, call `open()` again for the next MIP level and pass `ImageInput::AppendMIPLevel` as the value for the *mode* argument, and then write the pixels of the subsequent MIP level. (See Section [ImageOutput Class Reference](#) for the full technical description of the arguments to `open()`.) The `close()` routine is called just once, after all subimages and MIP levels are completed.

Below is pseudocode for writing a MIP-map (a multi-resolution image used for texture mapping):

C++

```

const char *filename = "foo.tif";
const int xres = 512, yres = 512;

```

(continues on next page)

(continued from previous page)

```

const int channels = 3; // RGB
unsigned char *pixels = new unsigned char [xres*yres*channels];

// Create the ImageOutput
auto out = ImageOutput::create (filename);

// Be sure we can support either mipmaps or subimages
if (! out->supports ("mipmap") && ! out->supports ("multiimage")) {
    std::cerr << "Cannot write a MIP-map\n";
    return;
}

// Set up spec for the highest resolution
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);

// Use Create mode for the first level.
ImageOutput::OpenMode appendmode = ImageOutput::Create;

// Write images, halving every time, until we're down to
// 1 pixel in either dimension
while (spec.width >= 1 && spec.height >= 1) {
    out->open (filename, spec, appendmode);
    out->write_image (TypeDesc::UINT8, pixels);
    // Assume halve() resamples the image to half resolution
    halve (pixels, spec.width, spec.height);
    // Don't forget to change spec for the next iteration
    spec.width /= 2;
    spec.height /= 2;

    // For subsequent levels, change the mode argument to
    // open(). If the format doesn't support MIPmaps directly,
    // try to emulate it with subimages.
    if (out->supports ("mipmap"))
        appendmode = ImageOutput::AppendMIPLevel;
    else
        appendmode = ImageOutput::AppendSubimage;
}
out->close ();

```

Python

```

filename = "foo.tif"
xres = 512
yres = 512
channels = 3 # RGB
pixels = numpy.array([yres, xres, channels], dtype='uint8')

# Create the ImageOutput
out = ImageOutput.create (filename)

# Be sure we can support either mipmaps or subimages
if not out.supports ("mipmap") and not out.supports ("multiimage") :
    print("Cannot write a MIP-map")

```

(continues on next page)

(continued from previous page)

```

    return
# Set up spec for the highest resolution
spec = ImageSpec(xres, yres, channels, "uint8")

# Use Create mode for the first level.
appendmode = "Create"

# Write images, halving every time, until we're down to
# 1 pixel in either dimension
while spec.width >= 1 and spec.height >= 1 :
    out.open (filename, spec, appendmode)
    out.write_image (pixels)
    # Assume halve() resamples the image to half resolution
    halve (pixels, spec.width, spec.height)
    # Don't forget to change spec for the next iteration
    spec.width = spec.width // 2
    spec.height = spec.height // 2

    # For subsequent levels, change the mode argument to
    # open(). If the format doesn't support MIPmaps directly,
    # try to emulate it with subimages.
    if (out.supports("mipmap"))
        appendmode = ImageOutput.AppendMIPLevel
    else
        appendmode = ImageOutput.AppendSubimage
out.close ()

```

In this example, we have used `write_image()`, but of course `write_scanline()`, `write_tile()`, and `write_rectangle()` work as you would expect, on the current MIP level.

3.2.9 Per-channel formats

Some image formats allow separate per-channel data formats (for example, half data for colors and float data for depth). When this is desired, the following steps are necessary:

1. Verify that the writer supports per-channel formats by checking `supports ("channelformats")`.
2. The `ImageSpec` passed to `open()` should have its `channelformats` vector filled with the types for each channel.
3. The call to `write_scanline()`, `read_scanlines()`, `write_tile()`, `write_tiles()`, or `write_image()` should pass a data pointer to the raw data, already in the native per-channel format of the file and contiguously packed, and specify that the data is of type `TypeUnknown`.

For example, the following code fragment will write a 5-channel image to an OpenEXR file, consisting of R/G/B/A channels in half and a Z channel in float:

```

// Mixed data type for the pixel
struct Pixel { half r,g,b,a; float z; };
Pixel pixels[xres*yres];

auto out = ImageOutput::create ("foo.exr");

// Double check that this format accepts per-channel formats

```

(continues on next page)

(continued from previous page)

```

if (! out->supports("channelformats")) {
    return;
}

// Prepare an ImageSpec with per-channel formats
ImageSpec spec (xres, yres, 5, TypeDesc::FLOAT);
spec.channelformats.assign(
    { TypeHalf, TypeHalf, TypeHalf, TypeHalf, TypeFloat });
spec.channelnames.assign({ "R", "G", "B", "A", "Z" });
spec.alpha_channel = 3;
spec.z_channel = 4;

out->open (filename, spec);
out->write_image (TypeDesc::UNKNOWN, /* use channel formats */
    pixels, /* data buffer */
    sizeof(Pixel)); /* pixel stride */

```

3.2.10 Writing “deep” data

Some image file formats (OpenEXR only, at this time) support the concept of “deep” pixels – those containing multiple samples per pixel (and a potentially differing number of them in each pixel). You can tell if a format supports deep images by checking `supports("deepdata")`, and you can specify a deep data in an `ImageSpec` by setting its `deep` field will be true.

Deep files cannot be written with the usual `write_scanline()`, `write_scanlines()`, `write_tile()`, `write_tiles()`, `write_image()` functions, due to the nature of their variable number of samples per pixel. Instead, `ImageOutput` has three special member functions used only for writing deep data:

```

bool write_deep_scanlines (int ybegin, int yend, int z,
    const DeepData &deepdata);

bool write_deep_tiles (int xbegin, int xend, int ybegin, int yend,
    int zbegin, int zend, const DeepData &deepdata);

bool write_deep_image (const DeepData &deepdata);

```

It is only possible to write “native” data types to deep files; that is, there is no automatic translation into arbitrary data types as there is for ordinary images. All three of these functions are passed deep data in a special `DeepData` structure, described in detail in Section “*Deep*” pixel data: *DeepData*.

Here is an example of using these methods to write a deep image:

C++

```

// Prepare the spec for 'half' RGBA, 'float' z
int nchannels = 5;
ImageSpec spec (xres, yres, nchannels);
spec.channelnames.assign({ "R", "G", "B", "A", "Z" });
spec.channeltypes.assign ({ TypeHalf, TypeHalf, TypeHalf, TypeHalf,
    TypeFloat });

spec.alpha_channel = 3;
spec.z_channel = 4;

```

(continues on next page)

(continued from previous page)

```

spec.deep = true;

// Prepare the data (sorry, complicated, but need to show the gist)
DeepData deepdata;
deepdata.init (spec);
for (int y = 0; y < yres; ++y)
    for (int x = 0; x < xres; ++x)
        deepdata.set_samples(y*xres+x, ...samples for that pixel...);
deepdata.alloc (); // allocate pointers and data
int pixel = 0;
for (int y = 0; y < yres; ++y)
    for (int x = 0; x < xres; ++x, ++pixel)
        for (int chan = 0; chan < nchannels; ++chan)
            for (int samp = 0; samp < deepdata.samples(pixel); ++samp)
                deepdata.set_deep_value (pixel, chan, samp, ...value...);

// Create the output
auto out = ImageOutput::create (filename);
if (! out)
    return;
// Make sure the format can handle deep data and per-channel formats
if (! out->supports("deepdata") || ! out->supports("channelformats"))
    return;

// Do the I/O (this is the easy part!)
out->open (filename, spec);
out->write_deep_image (deepdata);
out->close ();

```

Python

```

# Prepare the spec for 'half' RGBA, 'float' z
int nchannels = 5
spec = ImageSpec(xres, yres, nchannels)
spec.channelnames = ("R", "G", "B", "A", "Z")
spec.channeltypes = ("half", "half", "half", "half", "float")
spec.alpha_channel = 3
spec.z_channel = 4
spec.deep = True

# Prepare the data (sorry, complicated, but need to show the gist)
deepdata = DeepData()
deepdata.init (spec)
for y in range(yres) :
    for x in range(xres) :
        deepdata.set_samples(y*xres+x, ...samples for that pixel...)
deepdata.alloc() # allocate pointers and data
pixel = 0
for y in range(yres) :
    for x in range(xres) :
        for chan in range(nchannels) :
            for samp in range(deepdata.samples(pixel)) :

```

(continues on next page)

(continued from previous page)

```

        deepdata.set_deep_value (pixel, chan, samp, ...value...)
        pixel += 1

# Create the output
out = ImageOutput.create (filename)
if out is None :
    return
# Make sure the format can handle deep data and per-channel formats
if not out.supports("deepdata") or not out.supports("channelformats") :
    return

# Do the I/O (this is the easy part!)
out.open (filename, spec)
out.write_deep_image (deepdata)
out.close ()

```

3.2.11 Copying an entire image

Suppose you want to copy an image, perhaps with alterations to the metadata but not to the pixels. You could open an `ImageInput` and perform a `read_image()`, and open another `ImageOutput` and call `write_image()` to output the pixels from the input image. However, for compressed images, this may be inefficient due to the unnecessary decompression and subsequent re-compression. In addition, if the compression is *lossy*, the output image may not contain pixel values identical to the original input.

A special `copy_image()` method of `ImageOutput` is available that attempts to copy an image from an open `ImageInput` (of the same format) to the output as efficiently as possible without altering pixel values, if at all possible.

Not all format plugins will provide an implementation of `copy_image()` (in fact, most will not), but the default implementation simply copies pixels one scanline or tile at a time (with decompression/recompression) so it's still safe to call. Furthermore, even a provided `copy_image()` is expected to fall back on the default implementation if the input and output are not able to do an efficient copy. Nevertheless, this method is recommended for copying images so that maximal advantage will be taken in cases where savings can be had.

The following is an example use of `copy_image()` to transfer pixels without alteration while modifying the image description metadata:

C++

```

// Open the input file
auto in = ImageInput::open ("input.jpg");

// Make an output spec, identical to the input except for metadata
ImageSpec out_spec = in->spec();
out_spec.attribute ("ImageDescription", "My Title");

// Create the output file and copy the image
auto out = ImageOutput::create ("output.jpg");
out->open (output, out_spec);
out->copy_image (in);

// Clean up

```

(continues on next page)

(continued from previous page)

```
out->close ();  
in->close ();
```

Python

```
# Open the input file  
inp = ImageInput.open ("input.jpg")  
  
# Make an output spec, identical to the input except for metadata  
out_spec = inp.spec()  
out_spec.attribute ("ImageDescription", "My Title")  
  
# Create the output file and copy the image  
out = ImageOutput.create ("output.jpg")  
out.open (output, out_spec)  
out.copy_image (inp)  
  
# Clean up  
out.close ()  
inp.close ()
```

3.2.12 Opening for output with configuration settings/hints

Sometimes you will want to give the image file writer hints or requests related to *how to write the data*, hints which must be made in time for the initial opening of the file. For example, when writing to a file format that requires unassociated alpha, you may already have unpremultiplied colors to pass, rather than the more customary practice of passing associated colors and having them converted to unassociated while being output.

This is accomplished by setting certain metadata in the `ImageSpec` that is passed to `ImageOutput::open()`. These particular metadata entries will be understood to be hints that control choices about how to write the file, rather than as metadata to store in the file header.

Configuration hints are optional and advisory only – meaning that not all image file writers will respect them (and indeed, many of them are only sensible for certain file formats).

Some common output configuration hints that tend to be respected across many writers (but not all, check Chapter *Bundled ImageIO Plugins* to see what hints are supported by each writer, as well as writer-specific settings) are:

Input Configuration Attribute	Type	Meaning
Compression	string	Compression method (and sometimes quality level) to be used. Each output file format may have a different set of possible compression methods that are accepted.
oio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to a memory buffer.
oio:BitsPerSample	int	Requests that the data in the file use a particular bits-per-sample that is not directly expressible by the <code>ImageSpec.format</code> or any of the usual C data types, for example, requesting 10 bits per sample in the output file.
oio:dither	int	If nonzero and writing <code>UINT8</code> values to the file from a source buffer of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oio:RawColor	int	If nonzero, when writing images to certain formats that support or dictate non-RGB color models (such as <code>YCbCr</code>), this indicates that the input passed by the app will already be in this color model, and should not be automatically converted from RGB to the designated color space as the pixels are written.
oio:UnassociatedAlpha	int	If nonzero and writing to a file format that allows or dictates unassociated alpha/color values, this hint indicates that the pixel data that will be passed are already in unassociated form and should not automatically be “un-premultiplied” by the writer in order to conform to the file format’s need for unassociated data.

Examples:

Below is an example where we are writing to a PNG file, which dictates that RGBA data is always unassociated (i.e., the color channels are not already premultiplied by alpha), and we already have unassociated pixel values we wish to write unaltered, without it assuming that it’s associated and automatically converting to unassociated alpha:

C++

```
unsigned char unassociated_pixels[xres*yres*channels];

ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);
spec["oio:UnassociatedAlpha"] = 1;

auto out = ImageOutput::create ("foo.png");
out->open ("foo.png", spec);
out->write_image (TypeDesc::UINT8, unassociated_pixels);
out->close ();
```

Python

```
# Prepare the spec that describes the file, but also add to it
# the hint that says that the pixel data we will send it will
# be already unassociated.
spec = ImageSpec (xres, yres, channels, "uint8")
spec["oio:UnassociatedAlpha"] = 1

out = ImageOutput.create ("foo.png")
```

(continues on next page)

(continued from previous page)

```
out.open ("foo.png", spec)
out.write_image (unassociated_pixels)
out.close ()
```

3.2.13 Custom I/O proxies (and writing the file to a memory buffer)

Some file format writers allow you to supply a custom I/O proxy object that can allow bypassing the usual file I/O with custom behavior, including the ability to fill an in-memory buffer with a byte-for-byte representation of the correctly formatted file that would have been written to disk.

Only some output format writers support this feature. To find out if a particular file format supports this feature, you can create an `ImageOutput` of the right type, and check if it supports the feature name "iopproxy":

```
auto out = ImageOutput::create (filename);
if (! out || ! out->supports ("iopproxy")) {
    return;
}
```

`ImageOutput` writers that support "iopproxy" will respond to a special attribute, "oio:iopproxy", which passes a pointer to a `Filesystem::IOProxy*` (see OpenImageIO's `filesystem.h` for this type and its subclasses). `IOProxy` is an abstract type, and concrete subclasses include `IOFile` (which wraps I/O to an open `FILE*`) and `IOVecOutput` (which sends output to a `std::vector<unsigned char>`).

Here is an example of using a proxy that writes the "file" to a `std::vector<unsigned char>`:

```
// ImageSpec describing the image we want to write.
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);

std::vector<unsigned char> file_buffer; // bytes will go here
Filesystem::IOVecOutput vecout (file_buffer); // I/O proxy object

auto out = ImageOutput::create ("out.exr", &vecout);
out->open ("out.exr", spec);
out->write_image (...);
out->close ();

// At this point, file_buffer will contain the "file"
```

3.2.14 Custom search paths for plugins

When you call `ImageOutput::create()`, the OpenImageIO library will try to find a plugin that is able to write the format implied by your filename. These plugins are alternately known as DLL's on Windows (with the `.dll` extension), DSO's on Linux (with the `.so` extension), and dynamic libraries on Mac OS X (with the `.dylib` extension).

OpenImageIO will look for matching plugins according to *search paths*, which are strings giving a list of directories to search, with each directory separated by a colon `:`. Within a search path, any substrings of the form `${F00}` will be replaced by the value of environment variable `F00`. For example, the searchpath `"${HOME}/plugins:/shared/plugins"` will first check the directory `/home/tom/plugins` (assuming the user's home directory is `/home/tom`), and if not found there, will then check the directory `/shared/plugins`.

The first search path it will check is that stored in the environment variable `OPENIMAGEIO_PLUGIN_PATH`. It will check each directory in turn, in the order that they are listed in the variable. If no adequate plugin is found in any of the

directories listed in this environment variable, then it will check the custom searchpath passed as the optional second argument to `ImageOutput::create()`, searching in the order that the directories are listed. Here is an example:

```
char *mysearch = "/usr/myapp/lib:${HOME}/plugins";
std::unique_ptr<ImageOutput> out = ImageOutput::create (filename, mysearch);
...
```

3.2.15 Error checking

Nearly every `ImageOutput` API function returns a `bool` indicating whether the operation succeeded (`true`) or failed (`false`). In the case of a failure, the `ImageOutput` will have saved an error message describing in more detail what went wrong, and the latest error message is accessible using the `ImageOutput` method `geterror()`, which returns the message as a `std::string`.

The exception to this rule is `ImageOutput::create()`, which returns `NULL` if it could not create an appropriate `ImageOutput`. And in this case, since no `ImageOutput` exists for which you can call its `geterror()` function, there exists a global `geterror()` function (in the `OpenImageIO` namespace) that retrieves the latest error message resulting from a call to `create()`.

Here is another version of the simple image writing code from Section *Image Output Made Simple*, but this time it is fully elaborated with error checking and reporting:

C++

```
#include <OpenImageIO/imageio.h>
using namespace OIIO;
...

const char *filename = "foo.jpg";
const int xres = 640, yres = 480;
const int channels = 3; // RGB
unsigned char pixels[xres*yres*channels];

auto out = ImageOutput::create (filename);
if (! out) {
    std::cerr << "Could not create an ImageOutput for "
               << filename << ", error = "
               << OpenImageIO::geterror() << "\n";
    return;
}
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);

if (! out->open (filename, spec)) {
    std::cerr << "Could not open " << filename
               << ", error = " << out->geterror() << "\n";
    return;
}

if (! out->write_image (TypeDesc::UINT8, pixels)) {
    std::cerr << "Could not write pixels to " << filename
               << ", error = " << out->geterror() << "\n";
    return;
}
```

(continues on next page)

(continued from previous page)

```
if (! out->close ()) {
    std::cerr << "Error closing " << filename
               << ", error = " << out->geterror() << "\n";
    return;
}
```

Python

```
from OpenImageIO import ImageOutput, ImageSpec
import numpy as np

filename = "foo.jpg"
xres = 640
yres = 480
channels = 3 # RGB
pixels = np.zeros((yres, xres, channels), dtype=np.uint8)

out = ImageOutput.create(filename)
if not out :
    print("Could not create an ImageOutput for", filename,
          ", error = ", OpenImageIO.geterror())
    return
spec = ImageSpec(xres, yres, channels, 'uint8')

if not out.open(filename, spec) :
    print("Could not open", filename, ", error = ", out.geterror())
    return

if not out.write_image(pixels) :
    print("Could not write pixels to", filename, ", error = ",
          out.geterror())
    return

if not out.close() :
    print("Error closing", filename, ", error = ", out.geterror())
    return
```

3.3 ImageOutput Class Reference

class **ImageOutput**

ImageOutput abstracts the writing of an image file in a file format-agnostic manner.

Users don't directly declare these. Instead, you call the `create()` static method, which will return a `unique_ptr` holding a subclass of *ImageOutput* that implements writing the particular format.

Opening and closing files for output

enum **OpenMode**

Modes passed to the *open()* call.

Values:

enumerator **Create**

enumerator **AppendSubimage**

enumerator **AppendMIPLevel**

inline virtual int **supports**(string_view feature) const

Given the name of a “feature”, return whether this *ImageOutput* supports output of images with the given properties. Most queries will simply return 0 for “doesn’t support” and 1 for “supports it,” but it is acceptable to have queries return other nonzero integers to indicate varying degrees of support or limits (but should be clearly documented as such).

Feature names that *ImageOutput* implementations are expected to recognize include:

- "tiles" : Is this format writer able to write tiled images?
- "rectangles" : Does this writer accept arbitrary rectangular pixel regions (via *write_rectangle()*)? Returning 0 indicates that pixels must be transmitted via *write_scanline()* (if scanline-oriented) or *write_tile()* (if tile-oriented, and only if *supports("tiles")* returns true).
- "random_access" : May tiles or scanlines be written in any order (0 indicates that they *must* be in successive order)?
- "multiimage" : Does this format support multiple subimages within a file?
- "appendsubimage" : Does this format support multiple subimages that can be successively appended at will via *open(name, spec, AppendSubimage)*? A value of 0 means that the format requires pre-declaring the number and specifications of the subimages when the file is first opened, with *open(name, subimages, specs)*.
- "mipmap" : Does this format support multiple resolutions for an image/subimage?
- "volumes" : Does this format support “3D” pixel arrays (a.k.a. volume images)?
- "alpha" : Can this format support an alpha channel?
- "nchannels" : Can this format support arbitrary number of channels (beyond RGBA)?
- "rewrite" : May the same scanline or tile be sent more than once? Generally, this is true for plugins that implement interactive display, rather than a saved image file.
- "empty" : Does this plugin support passing a NULL data pointer to the various *write* routines to indicate that the entire data block is composed of pixels with value zero? Plugins that support this achieve a speedup when passing blank scanlines or tiles (since no actual data needs to be transmitted or converted).
- "channelformats" : Does this format writer support per-channel data formats, respecting the *ImageSpec*’s *channelformats* field? If not, it only accepts a single data format for all channels and will ignore the *channelformats* field of the spec.

- "displaywindow" : Does the format support display ("full") windows distinct from the pixel data window?
- "origin" : Does the image format support specifying a pixel window origin (i.e., nonzero *ImageSpec* x, y, z)?
- "negativeorigin" : Does the image format allow data and display window origins (i.e., *ImageSpec* x, y, z, full_x, full_y, full_z) to have negative values?
- "deepdata" : Does the image format allow "deep" data consisting of multiple values per pixel (and potentially a differing number of values from pixel to pixel)?
- "arbitrary_metadata" : Does the image file format allow metadata with arbitrary names (and either arbitrary, or a reasonable set of, data types)? (Versus the file format supporting only a fixed list of specific metadata names/values.)
- "exif" Does the image file format support Exif camera data (either specifically, or via arbitrary named metadata)?
- "iptc" Does the image file format support IPTC data (either specifically, or via arbitrary named metadata)?
- "iopproxy" Does the image file format support writing to an IOProxy?
- "procedural" : Is this a purely procedural output that doesn't write an actual file?
- "thumbnail" : Does this format writer support adding a reduced resolution copy of the image via the `thumbnail()` method?
- "thumbnail_after_write" : Does this format writer support calling `thumbnail()` after the scan-lines or tiles have been specified? (Supporting "thumbnail" but not "thumbnail_after_write" means that any thumbnail must be supplied immediately after `open()`, prior to any of the `write_*` calls.)
- "noimage" : Does this format allow 0x0 sized images, i.e. an image file with metadata only and no pixels?

This list of queries may be extended in future releases. Since this can be done simply by recognizing new query strings, and does not require any new API entry points, addition of support for new queries does not break 'link compatibility' with previously-compiled plugins.

virtual bool **open**(const std::string &filename, const *ImageSpec* &newspec, *OpenMode* mode = Create) = 0

Open the file with given name, with resolution and other format data as given in newspec. It is legal to call open multiple times on the same file without a call to `close()`, if it supports multiimage and mode is AppendSubimage, or if it supports MIP-maps and mode is AppendMIPLevel — this is interpreted as appending a subimage, or a MIP level to the current subimage, respectively.

Parameters

- **filename** – The name of the image file to open, UTF-8 encoded.
- **newspec** – The *ImageSpec* describing the resolution, data types, etc.
- **mode** – Specifies whether the purpose of the open is to create/truncate the file (default: Create), append another subimage (AppendSubimage), or append another MIP level (AppendMIPLevel).

Returns

true upon success, or false upon failure.

inline bool **open**(const std::wstring &filename, const *ImageSpec* &newspec, *OpenMode* mode = Create)

Open an *ImageOutput* using a UTF-16 encoded wstring filename.

inline virtual bool **open**(const std::string &filename, int subimages, const *ImageSpec* *specs)

Open a multi-subimage file with given name and specifications for each of the subimages. Upon success, the first subimage will be open and ready for transmission of pixels. Subsequent subimages will be denoted with the usual call of `open(name, spec, AppendSubimage)` (and MIP levels by `open(name, spec, AppendMIPLevel)`).

The purpose of this call is to accommodate format-writing libraries that must know the number and specifications of the subimages upon first opening the file; such formats can be detected by: `supports("multiimage") && !supports("appendsubimage")` The individual specs passed to the appending *open()* calls for subsequent subimages *must* match the ones originally passed.

Parameters

- **filename** – The name of the image file to open, UTF-8 encoded.
- **subimages** – The number of subimages (and therefore the length of the `specs[]` array.
- **specs[]** – Pointer to an array of *ImageSpec* objects describing each of the expected subimages.

Returns

`true` upon success, or `false` upon failure.

inline const *ImageSpec* &**spec**(void) const

Return a reference to the image format specification of the current subimage. Note that the contents of the spec are invalid before *open()* or after *close()*.

virtual bool **close**() = 0

Closes the currently open file associated with this *ImageOutput* and frees any memory or resources associated with it.

Helper functions for ImageOutput implementations.

This set of utility functions are not meant to be called by user code. They are protected methods of *ImageOutput*, and are used internally by the *ImageOutput* implementation to help it properly implement support of IOProxy.

Creating an ImageOutput

static *unique_ptr* **create**(string_view filename, Filesystem::IOProxy *ioprox = nullptr, string_view plugin_searchpath = "")

Create an *ImageOutput* that can be used to write an image file. The type of image file (and hence, the particular subclass of *ImageOutput* returned, and the plugin that contains its methods) is inferred from the name, if it appears to be a full filename, or it may also name the format.

Parameters

- **filename** – The name of the file format (e.g., "openexr"), a file extension (e.g., "exr"), or a filename from which the file format can be inferred from its extension (e.g., "hawaii.exr"). The filename is UTF-8 encoded.
- **plugin_searchpath** – An optional colon-separated list of directories to search for OpenImageIO plugin DSO/DLL's.
- **ioprox** – Optional pointer to an IOProxy to use (not supported by all formats, see `supports("ioprox")`). The caller retains ownership of the proxy.

Returns

A `unique_ptr` that will close and free the *ImageOutput* when it exits scope or is reset. The pointer will be empty if the required writer was not able to be created.

```
static inline unique_ptr create(const std::wstring &filename, Filesystem::IOProxy *ioprox = nullptr, const  
                                std::wstring &plugin_searchpath = {})
```

Create an *ImageOutput* using a UTF-16 encoded wstring filename and plugin searchpath.

IOProxy aids for ImageOutput implementations.

This set of utility functions are not meant to be called by user code. They are protected methods of *ImageOutput*, and are used internally by the *ImageOutput* implementation to help it properly implement support of IOProxy.

Writing pixels

Common features of all the `write` methods:

- The `format` parameter describes the data type of the data[]. The write methods automatically convert the data from the specified `format` to the actual output data type of the file (as was specified by the *ImageSpec* passed to *open()*). If `format` is `TypeUnknown`, then rather than converting from `format`, it will just copy pixels assumed to already be in the file's native data layout (including, possibly, per-channel data formats as specified by the *ImageSpec*'s `channelformats` field).
- The stride values describe the layout of the data buffer: `xstride` is the distance in bytes between successive pixels within each scanline. `ystride` is the distance in bytes between successive scanlines. For volumetric images `zstride` is the distance in bytes between successive "volumetric planes". Strides set to the special value `AutoStride` imply contiguous data, i.e.,

```
xstride = format.size() * nchannels  
ystride = xstride * width  
zstride = ystride * height
```

- Any `range` parameters (such as `ybegin` and `yend`) describe a "half open interval", meaning that `begin` is the first item and `end` is *one past the last item*. That means that the number of items is `end - begin`.
- For ordinary 2D (non-volumetric) images, any `z` or `zbegin` coordinates should be 0 and any `zend` should be 1, indicating that only a single image "plane" exists.
- Scanlines or tiles must be written in successive increasing coordinate order, unless the particular output file driver allows random access (indicated by `supports("random_access")`).
- All write functions return `true` for success, `false` for failure (after which a call to *geterror()* may retrieve a specific error message).

```
virtual bool write_scanline(int y, int z, TypeDesc format, const void *data, stride_t xstride = AutoStride)
```

Write the full scanline that includes pixels (*,y,z). For 2D non-volume images, `z` should be 0. The `xstride` value gives the distance between successive pixels (in bytes). Strides set to `AutoStride` imply "contiguous" data.

Parameters

- **y/z** – The y & z coordinates of the scanline.
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.

- **xstride** – The distance in bytes between successive pixels in data (or `AutoStride`).

Returns

true upon success, or false upon failure.

virtual bool **write_scanlines**(int ybegin, int yend, int z, *TypeDesc* format, const void *data, stride_t xstride = `AutoStride`, stride_t ystride = `AutoStride`)

Write multiple scanlines that include pixels (*,y,z) for all ybegin <= y < yend, from data. This is analogous to `write_scanline(y, z, format, data, xstride)` repeatedly for each of the scanlines in turn (the advantage, though, is that some image file types may be able to write multiple scanlines more efficiently or in parallel, than it could with one scanline at a time).

Parameters

- **ybegin/yend** – The y range of the scanlines being passed.
- **z** – The z coordinate of the scanline.
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.
- **xstride/ystride** – The distance in bytes between successive pixels and scanlines (or `AutoStride`).

Returns

true upon success, or false upon failure.

virtual bool **write_tile**(int x, int y, int z, *TypeDesc* format, const void *data, stride_t xstride = `AutoStride`, stride_t ystride = `AutoStride`, stride_t zstride = `AutoStride`)

Write the tile with (x,y,z) as the upper left corner. The three stride values give the distance (in bytes) between successive pixels, scanlines, and volumetric slices, respectively. Strides set to `AutoStride` imply ‘contiguous’ data in the shape of a full tile, i.e.,

```
xstride = format.size() * spec.nchannels
ystride = xstride * spec.tile_width
zstride = ystride * spec.tile_height
```

Note: This call will fail if the image is not tiled, or if (x,y,z) is not the upper left corner coordinates of a tile.

Parameters

- **x/y/z** – The upper left coordinate of the tile being passed.
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.
- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes (or `AutoStride` to indicate a “contiguous” single tile).

Returns

true upon success, or false upon failure.

virtual bool **write_tiles**(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, *TypeDesc* format, const void *data, stride_t xstride = `AutoStride`, stride_t ystride = `AutoStride`, stride_t zstride = `AutoStride`)

Write the block of multiple tiles that include all pixels in

`[xbegin,xend) X [ybegin,yend) X [zbegin,zend)`

This is analogous to calling `write_tile(x,y,z,...)` for each tile in turn (but for some file formats, passing multiple tiles may allow it to write more efficiently or in parallel).

The begin/end pairs must correctly delineate tile boundaries, with the exception that it may also be the end of the image data if the image resolution is not a whole multiple of the tile size. The stride values give the data spacing of adjacent pixels, scanlines, and volumetric slices (measured in bytes). Strides set to `AutoStride` imply contiguous data in the shape of the `[begin,end)` region, i.e.,

```
xstride = format.size() * spec.nchannels
ystride = xstride * (xend-xbegin)
zstride = ystride * (yend-ybegin)
```

Note: The call will fail if the image is not tiled, or if the pixel ranges do not fall along tile (or image) boundaries, or if it is not a valid tile range.

Parameters

- **xbegin/xend** – The x range of the pixels covered by the group of tiles passed.
- **ybegin/yend** – The y range of the pixels covered by the tiles.
- **zbegin/zend** – The z range of the pixels covered by the tiles (for a 2D image, `zbegin=0` and `zend=1`).
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.
- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes (or `AutoStride`).

Returns

true upon success, or false upon failure.

virtual bool **write_rectangle**(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, *TypeDesc* format, const void *data, stride_t xstride = `AutoStride`, stride_t ystride = `AutoStride`, stride_t zstride = `AutoStride`)

Write a rectangle of pixels given by the range

`[xbegin,xend) X [ybegin,yend) X [zbegin,zend)`

The stride values give the data spacing of adjacent pixels, scanlines, and volumetric slices (measured in bytes). Strides set to `AutoStride` imply contiguous data in the shape of the `[begin,end)` region, i.e.,

```
xstride = format.size() * spec.nchannels
ystride = xstride * (xend-xbegin)
zstride = ystride * (yend-ybegin)
```

Note: The call will fail for a format plugin that does not return true for `supports("rectangles")`.

Parameters

- **xbegin/xend** – The x range of the pixels being passed.
- **ybegin/yend** – The y range of the pixels being passed.
- **zbegin/zend** – The z range of the pixels being passed (for a 2D image, zbegin=0 and zend=1).
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.
- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes (or *AutoStride*).

Returns

true upon success, or false upon failure.

```
virtual bool write_image(TypeDesc format, const void *data, stride_t xstride = AutoStride, stride_t ystride =
    AutoStride, stride_t zstride = AutoStride, ProgressCallback progress_callback =
    nullptr, void *progress_callback_data = nullptr)
```

Write the entire image of `spec.width` x `spec.height` x `spec.depth` pixels, from a buffer with the given strides and in the desired format.

Depending on the spec, this will write either all tiles or all scanlines. Assume that data points to a layout in row-major order.

Because this may be an expensive operation, a progress callback may be passed. Periodically, it will be called as follows:

```
progress_callback (progress_callback_data, float done);
```

where done gives the portion of the image (between 0.0 and 1.0) that has been written thus far.

Parameters

- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.
- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes (or *AutoStride*).
- **progress_callback/progress_callback_data** – Optional progress callback.

Returns

true upon success, or false upon failure.

```
virtual bool write_deep_scanlines(int ybegin, int yend, int z, const DeepData &deepdata)
```

Write deep scanlines containing pixels (*,y,z), for all y in the range [ybegin,yend), to a deep file. This will fail if it is not a deep file.

Parameters

- **ybegin/yend** – The y range of the scanlines being passed.
- **z** – The z coordinate of the scanline.
- **deepdata** – A *DeepData* object with the data for these scanlines.

Returns

true upon success, or false upon failure.

virtual bool **write_deep_tiles**(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, const *DeepData* &deepdata)

Write the block of deep tiles that include all pixels in the range

[xbegin,xend) X [ybegin,yend) X [zbegin,zend)

The begin/end pairs must correctly delineate tile boundaries, with the exception that it may also be the end of the image data if the image resolution is not a whole multiple of the tile size.

Note: The call will fail if the image is not tiled, or if the pixel ranges do not fall along tile (or image) boundaries, or if it is not a valid tile range.

Parameters

- **xbegin/xend** – The x range of the pixels covered by the group of tiles passed.
- **ybegin/yend** – The y range of the pixels covered by the tiles.
- **zbegin/zend** – The z range of the pixels covered by the tiles (for a 2D image, zbegin=0 and zend=1).
- **deepdata** – A *DeepData* object with the data for the tiles.

Returns

true upon success, or false upon failure.

virtual bool **write_deep_image**(const *DeepData* &deepdata)

Write the entire deep image described by deepdata. Depending on the spec, this will write either all tiles or all scanlines.

Parameters

deepdata – A *DeepData* object with the data for the image.

Returns

true upon success, or false upon failure.

inline virtual bool **set_thumbnail**(const ImageBuf &thumb)

Specify a reduced-resolution (“thumbnail”) version of the image. Note that many image formats may require the thumbnail to be specified prior to writing the pixels.

Note: This method was added to OpenImageIO 2.3.

Parameters

thumb – A reference to an ImageBuf containing the thumbnail image.

Returns

true upon success, false if it was not possible to write the thumbnail, or if this file format (or writer) does not support thumbnails.

Public Types

using **unique_ptr** = std::unique_ptr<*ImageOutput*>
 unique_ptr to an *ImageOutput*.

typedef *ImageOutput* *(***Creator**)()

Call signature of a function that creates and returns an *ImageOutput**.

Public Functions

virtual const char ***format_name**(void) const = 0

Return the name of the format implemented by this class.

virtual bool **copy_image**(*ImageInput* *in)

Read the pixels of the current subimage of *in*, and write it as the next subimage of **this*, in a way that is efficient and does not alter pixel values, if at all possible. Both *in* and *this* must be a properly-opened *ImageInput* and *ImageOutput*, respectively, and their current images must match in size and number of channels.

If a particular *ImageOutput* implementation does not supply a *copy_image* method, it will inherit the default implementation, which is to simply read scanlines or tiles from *in* and write them to **this*. However, some file format implementations may have a special technique for directly copying raw pixel data from the input to the output, when both are the same file type and the same pixel data type. This can be more efficient than *in*->*read_image*() followed by *out*->*write_image*(), and avoids any unintended pixel alterations, especially for formats that use lossy compression.

If the function fails and returns *false*, an error message can be retrieved from *this*->*geterror*(), even if the actual error was related to reading from *in* (i.e., reading errors are automatically transferred to **this*).

Note: this method is NOT thread-safe (against other threads that may also be using *in*), since it depends on persistent state in the *ImageInput*.

Parameters

in – A pointer to the open *ImageInput* to read from.

Returns

true upon success, or *false* upon failure.

virtual bool **set_ioproxy**(Filesystem::IOProxy *ioproxy)

Set an IOProxy for this writer. This must be called prior to *open*(), and only for writers that support them (supports("ioproxy")). The caller retains ownership of the proxy.

Returns

true for success, *false* for failure.

bool **has_error**() const

Is there a pending error message waiting to be retrieved, that resulted from an *ImageOutput* API call made by the this thread?

Note that any *error*() calls issued are thread-specific, and the *geterror*()/*has_error*() are expected to be called by the same thread that called whichever API function encountered an error.

std::string **geterror**(bool clear = true) const

Return the text of all pending error messages issued against this *ImageOutput* by the calling thread, and clear the pending error message unless *clear* is false. If no error message is pending, it will return an empty string.

Note that any `error()` calls issued are thread-specific, and the `geterror()/has_error()` are expected to be called by the same thread that called whichever API function encountered an error.

template<typename ...**Args**>

inline void **errorfmt**(const char *fmt, const *Args*&... args) const

Error reporting for the plugin implementation: call this with std::format-like arguments. It is not necessary to have the error message contain a trailing newline.

void **threads**(int n)

Set the threading policy for this *ImageOutput*, controlling the maximum amount of parallelizing thread “fan-out” that might occur during large write operations. The default of 0 means that the global `attribute("threads")` value should be used (which itself defaults to using as many threads as cores; see Section `Global Attributes_`).

The main reason to change this value is to set it to 1 to indicate that the calling thread should do all the work rather than spawning new threads. That is probably the desired behavior in situations where the calling application has already spawned multiple worker threads.

int **threads**() const

Retrieve the current thread-spawning policy.

See also:

threads(int)

virtual size_t **heapsize**() const

Memory tracking method. Return the total heap memory allocated by *ImageOutput*. Overridable version of `heapsize` defined in `memory.h`.

virtual size_t **footprint**() const

Memory tracking method. Return the total memory footprint of *ImageOutput*. Overridable version of `footprint` defined in `memory.h`.

IMAGEINPUT: READING IMAGES

4.1 Image Input Made Simple

Here is the simplest sequence required to open an image file, find out its resolution, and read the pixels (converting them into 8-bit values in memory, even if that's not the way they're stored in the file):

C++

```
#include <OpenImageIO/imageio.h>
using namespace OIIO;

void simple_read()
{
    const char* filename = "tahoe.tif";

    auto inp = ImageInput::open(filename);
    if (! inp)
        return;
    const ImageSpec &spec = inp->spec();
    int xres = spec.width;
    int yres = spec.height;
    int nchannels = spec.nchannels;
    auto pixels = std::unique_ptr<unsigned char[]>(new unsigned char[xres * yres *
↪nchannels]);
    inp->read_image(0, 0, 0, nchannels, TypeDesc::UINT8, &pixels[0]);
    inp->close();
}
```

Python

```
import OpenImageIO as oiio
def simple_read():
    filename = "tahoe.tif"

    inp = oiio.ImageInput.open(filename)
    if inp :
        spec = inp.spec()
        xres = spec.width
        yres = spec.height
        nchannels = spec.nchannels
        pixels = inp.read_image(0, 0, 0, nchannels, "uint8")
        inp.close()
```

Here is a breakdown of what work this code is doing:

- Search for an ImageIO plugin that is capable of reading the file (`foo.jpg`), first by trying to deduce the correct plugin from the file extension, but if that fails, by opening every ImageIO plugin it can find until one will open the file without error. When it finds the right plugin, it creates a subclass instance of `ImageInput` that reads the right kind of file format, and tries to fully open the file. The `open()` method returns a `std::unique_ptr<ImageInput>` that will be automatically freed when it exits scope.

C++

```
auto inp = ImageInput::open (filename);
```

Python

```
inp = ImageInput.open (filename)
```

- The specification, accessible as `inp->spec()`, contains vital information such as the dimensions of the image, number of color channels, and data type of the pixel values. This is enough to allow us to allocate enough space for the image in C++ (for Python, this is unnecessary, since `read_image()` will return a NumPy array to us).

C++

```
const ImageSpec &spec = inp->spec();
int xres = spec.width;
int yres = spec.height;
int nchannels = spec.nchannels;
auto pixels = std::unique_ptr<unsigned char[]>(new unsigned char[xres * yres *
↪nchannels]);
```

Python

```
spec = inp.spec()
xres = spec.width
yres = spec.height
channels = spec.nchannels
```

Note that in this example, we don't care what data format is used for the pixel data in the file — we will request unsigned 8 bit integers and rely on OpenImageIO's ability to convert to our requested format from the native data format of the file.

- Read the entire image, hiding all details of the encoding of image data in the file, whether the file is scanline- or tile-based, or what is the native format of the data in the file (in this case, we request that it be automatically converted to unsigned 8-bit integers). Note that the exact set of channels are specified as well as the explicit subimage and miplevel for efficiency and thread-safety.

C++

```
inp->read_image(0, 0, 0, nchannels, TypeDesc::UINT8, &pixels[0]);
```

Python

```
pixels = inp->read_image(0, 0, 0, nchannels, "uint8")
# Note: pixels now contains a NumPy array of the image data.
```

- Close the file.

C++

```
inp->close();
```

Python

```
inp.close()
```

- When `inp` exits its scope, the `ImageInput` will automatically be destroyed and any resources used by the plugin will be released.

4.2 Advanced Image Input

Let's walk through some of the most common things you might want to do, but that are more complex than the simple example above.

4.2.1 Reading individual scanlines and tiles

The simple example of Section *Image Input Made Simple* read an entire image with one call. But sometimes you want to read a large image a little at a time and do not wish to retain the entire image in memory as you process it. OpenImageIO allows you to read images one scanline at a time or one tile at a time.

Examining the `ImageSpec` reveals whether the file is scanline or tile-oriented: a scanline image will have `spec.tile_width` and `spec.tile_height` set to 0, whereas a tiled images will have nonzero values for the tile dimensions.

Reading scanlines

Individual scanlines may be read using the `read_scanline()` API call:

C++

```
auto inp = ImageInput::open (filename);
const ImageSpec &spec = inp->spec();
if (spec.tile_width == 0) {
    auto scanline = std::unique_ptr<unsigned char[]>(new unsigned char[spec.width * spec.
    nchannels]);
    for (int y = 0; y < spec.height; ++y) {
        inp->read_scanline (y, 0, TypeDesc::UINT8, &scanline[0]);
        // ... process data in scanline[0..width*channels-1] ...
    }
} else {
    //... handle tiles, or reject the file ...
}
inp->close ();
```

Python

```
= oio.ImageInput.open (filename)
= inp.spec()
pec.tile_width == 0 :
for y in range(spec.height) :
    scanline = inp.read_scanline (y, 0, "uint8")
    # ... process data in scanline[0..width*channels-1] ...
```

(continues on next page)

(continued from previous page)

```
se :
# ... handle tiles, or reject the file ...
close ()
```

The first two arguments to `read_scanline()` specify which scanline is being read by its vertical (y) scanline number (beginning with 0) and, for volume images, its slice (z) number (the slice number should be 0 for 2D non-volume images). This is followed by a `TypeDesc` describing the data type of the pixel buffer you are supplying, and a pointer to the pixel buffer itself. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section [Data Strides](#)).

Nearly all `ImageInput` implementations will be most efficient reading scanlines in strict order (starting with scanline 0, then 1, up to `yres-1`, without skipping any). An `ImageInput` is required to accept `read_scanline()` requests in arbitrary order, but depending on the file format and reader implementation, out-of-order scanline reads may be inefficient.

There is also a `read_scanlines()` function that operates similarly, except that it takes a `ybegin` and `yend` that specify a range, reading all scanlines `ybegin <= y < yend`. For most image format readers, this is implemented as a loop over individual scanlines, but some image format readers may be able to read a contiguous block of scanlines more efficiently than reading each one individually.

The full descriptions of the `read_scanline()` and `read_scanlines()` functions may be found in Section [ImageInput Class Reference](#).

Reading tiles

Once you `open()` an image file, you can find out if it is a tiled image (and the tile size) by examining the `ImageSpec`'s `tile_width`, `tile_height`, and `tile_depth` fields. If they are zero, it's a scanline image and you should read pixels using `read_scanline()`, not `read_tile()`.

C++

```
auto inp = ImageInput::open(filename);
const ImageSpec &spec = inp->spec();
if (spec.tile_width == 0) {
    // ... read scanline by scanline ...
} else {
    // Tiles
    int tilesz = spec.tile_width * spec.tile_height;
    auto tile = std::unique_ptr<unsigned char[]>(new unsigned char[tilesz * spec.
    nchannels]);
    for (int y = 0; y < spec.height; y += spec.tile_height) {
        for (int x = 0; x < spec.width; x += spec.tile_width) {
            inp->read_tile(x, y, 0, TypeDesc::UINT8, &tile[0]);
            // ... process the pixels in tile[] ..
        }
    }
}
inp->close ();
```

Python

```
= oio.ImageInput.open(filename)
= inp.spec()
pec.tile_width == 0 :
```

(continues on next page)

(continued from previous page)

```
# ... read scanline by scanline ...
pass
:
# Tiles
tilesize = spec.tile_width * spec.tile_height
for y in range(0, spec.height, spec.tile_height) :
    for x in range(0, spec.width, spec.tile_width) :
        tile = inp.read_tile (x, y, 0, "uint8")
        # ... process the pixels in tile[][] ..
close ()
```

The first three arguments to `read_tile()` specify which tile is being read by the pixel coordinates of any pixel contained in the tile: `x` (column), `y` (scanline), and `z` (slice, which should always be 0 for 2D non-volume images). This is followed by a `TypeDesc` describing the data format of the pixel buffer you are supplying, and a pointer to the pixel buffer. Pixel data will be written to your buffer in order of increasing slice, increasing scanline within each slice, and increasing column within each scanline. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section [Data Strides](#)).

All `ImageInput` implementations are required to support reading tiles in arbitrary order (i.e., not in strict order of increasing `y` rows, and within each row, increasing `x` column, without missing any tiles).

The full description of the `read_tile()` function may be found in Section [ImageInput Class Reference](#).

4.2.2 Converting formats

The code examples of the previous sections all assumed that your internal pixel data is stored as unsigned 8-bit integers (i.e., 0-255 range). But `OpenImageIO` is significantly more flexible.

You may request that the pixels be stored in any of several formats. This is done merely by passing the `read` function the data type of your pixel buffer, as one of the enumerated type `TypeDesc`.

It is not required that the pixel data buffer passed to `read_image()`, `read_scanline()`, or `read_tile()` actually be in the same data format as the data in the file being read. `OpenImageIO` will automatically convert from native data type of the file to the internal data format of your choice. For example, the following code will open a TIFF and read pixels into your internal buffer represented as `float` values. This will work regardless of whether the TIFF file itself is using 8-bit, 16-bit, or float values.

C++

```
std::unique_ptr<ImageInput> inp = ImageInput::open ("myfile.tif");
const ImageSpec &spec = inp->spec();

int numpixels = spec.image_pixels();
int nchannels = spec.nchannels;
auto pixels = std::unique_ptr<float[]>(new float[numpixels * nchannels]);

inp->read_image (0, 0, 0, nchannels, TypeDesc::FLOAT, &pixels[0]);
```

Python

```
inp = ImageInput.open("myfile.tif")
pixels = inp.read_image(0, 0, 0, nchannels, "float")
```

Note that `read_scanline()` and `read_tile()` have a parameter that works in a corresponding manner.

You can, of course, find out the native type of the file simply by examining `spec.format`. If you wish, you may then allocate a buffer big enough for an image of that type and request the native type when reading, therefore eliminating any translation among types and seeing the actual numerical values in the file.

4.2.3 Data Strides

In the preceding examples, we have assumed that the buffer passed to the `read` functions (i.e., the place where you want your pixels to be stored) is *contiguous*, that is:

- each pixel in memory consists of a number of data values equal to the number of channels in the file;
- successive column pixels within a row directly follow each other in memory, with the first channel of pixel `x` immediately following last channel of pixel `x-1` of the same row;
- for whole images or tiles, the data for each row immediately follows the previous one in memory (the first pixel of row `y` immediately follows the last column of row `y-1`);
- for 3D volumetric images, the first pixel of slice `z` immediately follows the last pixel of slice `z-1`.

Please note that this implies that `read_tile()` will write pixel data into your buffer so that it is contiguous in the shape of a single tile, not just an offset into a whole image worth of pixels.

The `read_scanline()` function takes an optional `xstride` argument, and the `read_image()` and `read_tile()` functions take optional `xstride`, `ystride`, and `zstride` values that describe the distance, in *bytes*, between successive pixel columns, rows, and slices, respectively, of your pixel buffer. For any of these values that are not supplied, or are given as the special constant `AutoStride`, contiguity will be assumed.

By passing different stride values, you can achieve some surprisingly flexible functionality. A few representative examples follow:

- Flip an image vertically upon reading, by using *negative y stride*:

```
auto pixels = std::unique_ptr<unsigned char*>(new unsigned char[spec.width * spec.
    height * spec.nchannels]);
int scanlinesize = spec.width * spec.nchannels * sizeof(pixels[0]);
...
in->read_image (0, 0, 0, spec.nchannels,
                TypeDesc::UINT8,
                (char *)pixels+(yres-1)*scanlinesize, // offset to last
                AutoStride,                          // default x stride
                -scanlinesize,                        // special y stride
                AutoStride);                          // default z stride
```

- Read a tile into its spot in a buffer whose layout matches a whole image of pixel data, rather than having a one-tile-only memory layout:

```
int pixelsize = spec.nchannels * sizeof(pixels[0]);
int scanlinesize = spec.width * pixelsize;
...
in->read_tile (x, y, 0, TypeDesc::UINT8,
              (char *)pixels + y*scanlinesize + x*pixelsize,
              pixelsize,
              scanlinesize);
```

Please consult Section [ImageInput Class Reference](#) for detailed descriptions of the stride parameters to each `read` function.

4.2.4 Reading channels to separate buffers

While specifying data strides allows writing entire pixels to buffers with arbitrary layouts, it is not possible to separate those pixels into multiple buffers (i.e. to write image data to a separate or planar memory layout: RRRRGGGGBBBB instead of the interleaved RGBRGBRGBRGB).

A workaround for this is to call `read_scanlines`, `read_tiles` or `read_image` repeatedly with arguments `chbegin` and `chend` of `0 <= chbegin < spec.nchannels` and `chend == chbegin + 1`:

C++

```
// one buffer for all three channels
auto pixels = std::unique_ptr<unsigned char[]>(new unsigned char[spec.width * spec.
height * spec.nchannels]);

for (int channel = 0; channel < spec.nchannels; ++channel) {
    file->read_image(
        0, 0,
        // reading one channel at a time
        channel, channel + 1,
        TypeDesc::UINT8,
        // writing the data to offsets spaced `spec.width * spec.height`
        // apart
        &pixels[spec.width * spec.height * channel]);
}
```

Python

```
pixels = numpy.zeros((spec.nchannels, spec.height, spec.width), "uint8")
for channel in range(spec.nchannels) :
    pixels[channel] = file.read_image(0, 0, channel, channel + 1, "uint8")
```

For many formats, this is nearly as fast as reading the image with interleaved pixel data if the format stores the pixels in an interleaved layout and even slightly faster if the pixels are stored in separate planes in the file.

4.2.5 Reading metadata

The `ImageSpec` that is filled in by `ImageInput::open()` specifies all the common properties that describe an image: data format, dimensions, number of channels, tiling. However, there may be a variety of additional *metadata* that are present in the image file and could be queried by your application.

The remainder of this section explains how to query additional metadata in the `ImageSpec`. It is up to the `ImageInput` to read these from the file, if indeed the file format is able to carry additional data. Individual `ImageInput` implementations should document which metadata they read.

Channel names

In addition to specifying the number of color channels, the ImageSpec also stores the names of those channels in its `channelnames` field, which is a `std::vector<std::string>` in C++, or a tuple of strings in Python. Its length should always be equal to the number of channels (it's the responsibility of the ImageInput to ensure this).

Only a few file formats (and thus ImageInput implementations) have a way of specifying custom channel names, so most of the time you will see that the channel names follow the default convention of being named "R", "G", "B", and "A", for red, green, blue, and alpha, respectively.

Here is example code that prints the names of the channels in an image:

C++

```
auto inp = ImageInput::open (filename);
const ImageSpec &spec = inp->spec();
for (int i = 0; i < spec.nchannels; ++i)
    std::cout << "Channel " << i << " is "
               << spec.channelnames[i] << "\n";
```

Python

```
inp = ImageInput.open (filename)
spec = inp.spec()
for i in range(spec.nchannels) :
    print("Channel", i, "is", spec.channelnames[i])
```

Specially-designated channels

The ImageSpec contains two fields, `alpha_channel` and `z_channel`, which designate which channel numbers represent alpha and z depth, if any. If either is set to -1, it indicates that it is not known which channel is used for that data.

If you are doing something special with alpha or depth, it is probably safer to respect the `alpha_channel` and `z_channel` designations (if not set to -1) rather than merely assuming that, for example, channel 3 is always the alpha channel.

Arbitrary metadata

All other metadata found in the file will be stored in the ImageSpec's `extra_attribs` field, which is a `ParamValueList`, which is itself essentially a vector of `ParamValue` instances. Each `ParamValue` stores one meta-datum consisting of a name, type (specified by a `TypeDesc`), number of values, and data pointer.

If you know the name and type of a specific piece of metadata you want to use, you can retrieve it using the `ImageSpec::getattribute()` method. In C++, this copies the value into your variable and returns `true` if the attribute was found, or `false` if it was not. In Python, `getattribute()` simply returns the value of the attribute itself, or `None` if no match was found.

C++

```
auto in; = ImageInput::open(filename);
const ImageSpec &spec = inp->spec();
...
int orientation = 0;
bool ok = spec.getattribute("Orientation", TypeInt, &orientation);
```

(continues on next page)

(continued from previous page)

```

if (!ok) {
    std::cout << "No integer orientation in the file\n";
}

```

Python

```

inp = ImageInput.open (filename)
spec = inp.spec()

orientation = spec.getattribute("Orientation")
if orientation is None :
    print("No integer orientation in the file")

```

By convention, ImageInput plugins will save all integer metadata as 32-bit integers (TypeDesc::INT or TypeDesc::UINT), even if the file format dictates that a particular item is stored in the file as a 8- or 16-bit integer. This is just to keep client applications from having to deal with all the types. Since there is relatively little metadata compared to pixel data, there's no real memory waste of promoting all integer types to int32 metadata. Floating-point metadata and string metadata may also exist, of course.

For certain common types, there is an even simpler method for retrieving the metadata:

C++

```

int i = spec.get_int_attribute ("Orientation", 0);
float f = spec.get_float_attribute ("PixelAspectRatio", 1.0f);
std::string s = spec.get_string_attribute ("ImageDescription", "");

```

Python

```

i = spec.get_int_attribute ("Orientation", 0)
f = spec.get_float_attribute ("PixelAspectRatio", 1.0)
s = spec.get_string_attribute ("ImageDescription", "")

```

This method simply returns the value. The second argument is the default value to use if the attribute named is not found. These versions will do automatic type conversion as well — for example, if you ask for a float and the attribute is really an int, it will return the proper float for it; or if the attribute is a UINT16 and you call `get_int_attribute()`, it will succeed, promoting to an int.

And finally, another convenience method lets you treat the spec itself as an associative array or dictionary:

C++

```

// spec["key"].get<TYPE> tries to retrieve that type, or a default
// value (generally 0 or empty string) if not found.
int i = spec["Orientation"].get<int>();
float f = spec["PixelAspectRatio"].get<float>();
std::string s = spec["ImageDescription"].get<std::string>();

// An optional argument to get() lets you specify a different default
// value to return if the attribute is not found.
float f = spec["PixelAspectRatio"].get<float>(1.0f);

```

Python

```
# spec["key"] returns the attribute if present, or raises KeyError
# if not found.
i = spec["Orientation"]
f = spec["PixelAspectRatio"]
s = spec["ImageDescription"]

# spec.get("key", default=None) returns the attribute if present,
# or the default value if not found.
val = spec.get("Orientation", 1)
```

Note that when retrieving with this “dictionary” syntax, the C++ and Python behaviors are different: C++ requires a `get<TYPE>()` call to retrieve the full value, and a missing key will return a default value. Python will return the value directly (no `get()` needed), and a missing key will raise a `KeyError` exception.

It is also possible to step through all the metadata, item by item. This can be accomplished using the technique of the following example:

C++

```
for (const auto &p : spec.extra_attribs) {
    printf ("    %s: %s\n", p.name().c_str(), p.get_string().c_str());
}
```

Python

```
for p in spec.attribs :
    printf ("    ", p.name, ":", p.value)
```

Each individual `ImageInput` implementation should document the names, types, and meanings of all metadata attributes that they understand.

Color space hints

We certainly hope that you are using only modern file formats that support high precision and extended range pixels (such as OpenEXR) and keeping all your images in a linear color space. But you may have to work with file formats that dictate the use of nonlinear color values. This is prevalent in formats that store pixels only as 8-bit values, since 256 values are not enough to linearly represent colors without banding artifacts in the dim values.

The `ImageSpec::extra_attribs` field may store metadata that reveals the color space the image file in the `"oiio:ColorSpace"` attribute (see Section [Color information](#) for explanations of particular values).

The `ImageInput` sets the `"oiio:ColorSpace"` metadata in a purely advisory capacity — the read will not convert pixel values among color spaces. Many image file formats only support nonlinear color spaces (for example, JPEG/JFIF dictates use of sRGB). So your application should intelligently deal with gamma-corrected and sRGB input, at the very least.

The color space hints only describe color channels. You should assume that alpha or depth (z) channels (designated by the `alpha_channel` and `z_channel` fields, respectively) always represent linear values and should never be transformed by your application.

4.2.6 Multi-image files and MIP-maps

Some image file formats support multiple discrete subimages to be stored in one file, and/or multiple resolutions for each image to form a MIPmap. When you `open()` an `ImageInput`, it will by default point to the first (i.e., number 0) subimage in the file, and the highest resolution (level 0) MIP-map level. You can switch to viewing another subimage or MIP-map level using the `seek_subimage()` function:

C++

```
auto inp = ImageInput::open (filename);
int subimage = 1;
int miplevel = 0;
if (inp->seek_subimage (subimage, miplevel)) {
    ... process the subimage/miplevel ...
} else {
    ... no such subimage/miplevel ...
}
```

Python

```
inp = ImageInput.open(filename)
subimage = 1
miplevel = 0
if inp.seek_subimage (subimage, miplevel) :
    # ... process the subimage/miplevel ...
else :
    # ... no such subimage/miplevel ...
```

The `seek_subimage()` function takes three arguments: the index of the subimage to switch to (starting with 0), the MIPmap level (starting with 0 for the highest-resolution level), and a reference to an `ImageSpec`, into which will be stored the spec of the new subimage/miplevel. The `seek_subimage()` function returns `true` upon success, and `false` if no such subimage or MIP level existed. It is legal to visit subimages and MIP levels out of order; the `ImageInput` is responsible for making it work properly. It is also possible to find out which subimage and MIP level is currently being viewed, using the `current_subimage()` and `current_miplevel()` functions, which return the index of the current subimage and MIP levels, respectively.

Below is pseudocode for reading all the levels of a MIP-map (a multi-resolution image used for texture mapping) that shows how to read multi-image files:

C++

```
auto inp = ImageInput::open (filename);
int miplevel = 0;
while (inp->seek_subimage (0, miplevel)) {
    const ImageSpec &spec = inp->spec();
    int npixels = spec.width * spec.height;
    int nchannels = spec.nchannels;
    auto pixels = std::unique_ptr<unsigned char*>(new unsigned char[npixels *
    ↪nchannels]);
    inp->read_image(0, miplevel, 0, nchannels, TypeDesc::UINT8, pixels);

    // ... do whatever you want with this level, in pixels ...

    ++miplevel;
}
```

(continues on next page)

(continued from previous page)

```
// Note: we break out of the while loop when seek_subimage fails
// to find a next MIP level.

inp->close();
```

Python

```
inp = ImageInput::open (filename)
miplevel = 0
while inp.seek_subimage(0, miplevel) :
    spec = inp.spec()
    nchannels = spec.nchannels
    pixels = inp.read_image (0, miplevel, 0, nchannels, "uint8")

    # ... do whatever you want with this level, in pixels ...

    miplevel += 1
}
# Note: we break out of the while loop when seek_subimage fails
# to find a next MIP level.

inp.close()
```

In this example, we have used `read_image()`, but of course `read_scanline()` and `read_tile()` work as you would expect, on the current subimage and MIP level.

4.2.7 Per-channel formats

Some image formats allow separate per-channel data formats (for example, half data for colors and float data for depth). If you want to read the pixels in their true native per-channel formats, the following steps are necessary:

1. Check the ImageSpec's `channelformats` vector. If non-empty, the channels in the file do not all have the same format.
2. When calling `read_scanline`, `read_scanlines`, `read_tile`, `read_tiles`, or `read_image`, pass a format of `TypeUnknown` to indicate that you would like the raw data in native per-channel format of the file written to your data buffer.

For example, the following code fragment will read a 5-channel image to an OpenEXR file, consisting of R/G/B/A channels in half and a Z channel in float:

```
auto inp = ImageInput::open (filename);
const ImageSpec &spec = inp->spec();

// Allocate enough space
auto pixels = std::unique_ptr<unsigned char[]>(new unsigned char[spec.image_
↳bytes(true)]);
int nchannels = spec.nchannels;
inp->read_image(0, 0, 0, nchannels,
               TypeDesc::UNKNOWN, /* use native channel formats */
               pixels);           /* data buffer */

if (spec.channelformats.size() > 0) {
```

(continues on next page)

(continued from previous page)

```

    ... the buffer contains packed data in the native
        per-channel formats ...
} else {
    ... the buffer contains all data per spec.format ...
}

```

4.2.8 Reading “deep” data

Some image file formats (OpenEXR only, at this time) support the concept of “deep” pixels – those containing multiple samples per pixel (and a potentially differing number of them in each pixel). You can tell an image is “deep” from its ImageSpec: the deep field will be true.

Deep files cannot be read with the usual `read_scanline()`, `read_scanlines()`, `read_tile()`, `read_tiles()`, `read_image()` functions, due to the nature of their variable number of samples per pixel. Instead, ImageInput has three special member functions used only for reading deep data:

C++

```

bool read_native_deep_scanlines (int subimage, int miplevel,
                                int ybegin, int yend, int z,
                                int chbegin, int chend,
                                DeepData &deepdata);

bool read_native_deep_tiles (int subimage, int miplevel,
                             int xbegin, int xend, int ybegin, int yend,
                             int zbegin, int zend,
                             int chbegin, int chend, DeepData &deepdata);

bool read_native_deep_image (int subimage, int miplevel,
                             DeepData &deepdata);

```

Python

```

ImageInput.read_native_deep_scanlines (subimage, miplevel,
                                       ybegin, yend, z, chbegin, chend)

ImageInput.read_native_deep_tiles (subimage, miplevel, xbegin, xend,
                                   ybegin, yend, zbegin, zend, chbegin, chend)

ImageInput.read_native_deep_image (subimage, miplevel)

```

It is only possible to read “native” data types from deep files; that is, there is no automatic translation into arbitrary data types as there is for ordinary images. All three of these functions store the resulting deep data in a special DeepData structure, described in detail in Section [Reading “deep” data](#).

Here is an example of using these methods to read a deep image from a file and print all its values:

C++

```

auto inp = ImageInput::open (filename);
if (! inp)
    return;
const ImageSpec &spec = inp.spec();

```

(continues on next page)

(continued from previous page)

```

if (spec.deep) {
    DeepData deepdata;
    inp.read_native_deep_image (0, 0, deepdata);
    int p = 0; // absolute pixel number
    for (int y = 0; y < spec.height; ++y) {
        for (int x = 0; x < spec.width; ++x, ++p) {
            std::cout << "Pixel " << x << ", " << y << ":\n";
            if (deepdata.samples(p) == 0)
                std::cout << " no samples\n";
            else
                for (int c = 0; c < spec.nchannels; ++c) {
                    TypeDesc type = deepdata.channeltype(c);
                    std::cout << " " << spec.channelnames[c] << ": ";
                    void *ptr = deepdata.pointers[p*spec.nchannels+c]
                    for (int s = 0; s < deepdata.samples(p); ++s) {
                        if (type.basetype == TypeDesc::FLOAT ||
                            type.basetype == TypeDesc::HALF)
                            std::cout << deepdata.deep_value(p, c, s) << ' ';
                        else if (type.basetype == TypeDesc::UINT32)
                            std::cout << deepdata.deep_value_uint(p, c, s) << ' ';
                    }
                    std::cout << "\n";
                }
        }
    }
}
inp.close ();

```

Python

```

inp = ImageInput::open (filename)
if inp is None :
    return
spec = inp.spec()
if spec.deep :
    deepdata = inp.read_native_deep_image (0, 0)
    p = 0 # absolute pixel number
    for y in range(spec.height) :
        for x in range(spec.width) :
            print ("Pixel", x, ",", y, ":")
            if deepdata.samples(p) == 0 :
                print(" no samples")
            else :
                for c in range(spec.nchannels) :
                    type = deepdata.channeltype(c)
                    print (" ", spec.channelnames[c], ":")
                    for s in range(deepdata.samples(p) :
                        print (deepdata.deep_value(p, c, s), end="")
                    print("")
inp.close()

```

4.2.9 Opening for input with configuration settings/hints

Sometimes you will want to give the image file reader hints or requests for how to open the file or present its data, hints which must be made in time for the initial opening of the file. For example, in specific circumstances, you might want to request that an image with unassociated alpha *not* be automatically converted to associated alpha by multiplying the color channel values by the alpha (as would be customary by OIIO convention).

This is accomplished by using the `ImageInput::open()` or `ImageInput::create()` method varieties that take an additional `config` parameter. This is an `ImageSpec` object whose metadata contains the configuration hints.

Configuration hints are optional and advisory only – meaning that not all image file readers will respect them (and indeed, many of them are only sensible for certain file formats).

Some common input configuration hints that tend to be respected across many readers (but not all, check [Chapter Bundled ImageIO Plugins](#) to see what hints are supported by each reader) are:

Input Configuration Attribute	Type	Meaning
<code>oiio:ioproxy</code>	ptr	Pointer to a <code>Filesystem::IProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.
<code>oiio:RawColor</code>	int	If nonzero, reading images with non-RGB color models (such as YCbCr) will return unaltered pixel values (versus the default OIIO behavior of automatically converting to RGB).
<code>oiio:UnassociatedAlpha</code>	int	If nonzero, and the file contains unassociated alpha, this will cause the reader to leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).
<code>oiio:reorient</code>	int	If zero, disables any automatic reorientation that the reader may ordinarily do to present te pixels in the preferred display orientation.

Examples:

Below is an example where we wish to read in an RGBA image in a format that tends to store it as unassociated alpha, but we DON'T want it to automatically be converted to associated alpha.

C++

```
// Set up an ImageSpec that holds the configuration hints.
ImageSpec config;
config["oiio:UnassociatedAlpha"] = 1;

// Open the file, passing in the config.
auto inp = ImageInput::open (filename, config);
const ImageSpec &spec = inp->spec();
auto pixels = std::unique_ptr<unsigned char*>(new unsigned char[spec.image_
->pixels() * spec.nchannels]);
inp->read_image (0, 0, 0, spec.nchannels, TypeDesc::UINT8, pixels.data());
if (spec.get_int_attribute("oiio:UnassociatedAlpha"))
    printf("pixels holds unassociated alpha\n");
else
    printf("pixels holds associated alpha\n");
```

Python

```
# Set up an ImageSpec that holds the configuration hints.
config = ImageSpec()
```

(continues on next page)

(continued from previous page)

```

config["oiio:UnassociatedAlpha"] = 1

# Open the file, passing in the config.
inp = ImageInput.open (filename, config)
spec = inp.spec()
pixels = inp.read_image (0, 0, 0, spec.nchannels, "uint8")
if (spec["oiio:UnassociatedAlpha"] == 1)
    print("pixels holds unassociated alpha")
else
    print("pixels holds associated alpha")

```

4.2.10 Custom I/O proxies (and reading the file from a memory buffer)

Some file format readers allow you to supply a custom I/O proxy object that can allow bypassing the usual file I/O with custom behavior, including the ability to read the file from an in-memory buffer rather than reading from disk.

Only some input format readers support this feature. To find out if a particular file format supports this feature, you can create an ImageInput of the right type, and check if it supports the feature name "ioproxy":

```

auto in = ImageInput::create(filename);
if (! in || ! in->supports ("ioproxy")) {
    return;
}

```

ImageInput readers that support "ioproxy" will respond to a special attribute, "oiio:ioproxy", which passes a pointer to a `Filesystem::IOProxy*` (see OpenImageIO's `filesystem.h` for this type and its subclasses). `IOProxy` is an abstract type, and concrete subclasses include `IOFile` (which wraps I/O to an open `FILE*`) and `IOMemReader` (which reads input from a block of memory).

Here is an example of using a proxy that reads the "file" from a memory buffer:

```

const void *buf = ...;    // pointer to memory block
size_t size = ...;        // length of memory block
Filesystem::IOMemReader memreader (buf, size); // I/O proxy object

auto in = ImageInput::open ("in.exr", nullptr, &memreader);
in->read_image (...);
in->close();

// That will have read the "file" from the memory buffer

```

4.2.11 Custom search paths for plugins

Please see Section [Global Attributes](#) for discussion about setting the plugin search path via the `attribute()` function. For example:

C++

```

std::string mysearch = "/usr/myapp/lib:/home/jane/plugins";
OIIO::attribute ("plugin_searchpath", mysearch);
auto inp = ImageInput::open (filename);
// ...

```

Python

```
mysearch = "/usr/myapp/lib:/home/jane/plugins"
OpenImageIO.attribute ("plugin_searchpath", mysearch)
inp = ImageInput.open(filename)
# ...
```

4.2.12 Error checking

Nearly every ImageInput API function returns a bool indicating whether the operation succeeded (true) or failed (false). In the case of a failure, the ImageInput will have saved an error message describing in more detail what went wrong, and the latest error message is accessible using the ImageInput method `geterror()`, which returns the message as a `std::string`.

The exceptions to this rule are static methods such as the static `ImageInput::open()` and `ImageInput::create()`, which return an empty pointer if it could not create an appropriate ImageInput (and open it, in the case of `open()`). In such a case, since no ImageInput is returned for which you can call its `geterror()` function, there exists a global `geterror()` function (in the OpenImageIO namespace) that retrieves the latest error message resulting from a call to static `open()` or `create()`.

Here is another version of the simple image reading code from Section *Image Input Made Simple*, but this time it is fully elaborated with error checking and reporting:

C++

```
#include <OpenImageIO/imageio.h>
using namespace OIIO;

void error_checking()
{
    const char *filename = "tahoe.tif";
    auto inp = ImageInput::open (filename);
    if (! inp) {
        std::cerr << "Could not open " << filename
                    << ", error = " << OIIO::geterror() << "\n";
        return;
    }
    const ImageSpec &spec = inp->spec();
    int xres = spec.width;
    int yres = spec.height;
    int nchannels = spec.nchannels;
    auto pixels = std::unique_ptr<unsigned char[]>(new unsigned char[xres * yres *
↵nchannels]);

    if (! inp->read_image(0, 0, 0, nchannels, TypeDesc::UINT8, &pixels[0])) {
        std::cerr << "Could not read pixels from " << filename
                    << ", error = " << inp->geterror() << "\n";
        return;
    }

    if (! inp->close ()) {
        std::cerr << "Error closing " << filename
                    << ", error = " << inp->geterror() << "\n";
        return;
    }
}
```

(continues on next page)

(continued from previous page)

```

    }
}

```

Python

```

import OpenImageIO as oiio
import numpy as np

filename = "tahoe.tif"
inp = oiio.ImageInput.open(filename)
if inp is None :
    print("Could not open", filename, ", error =", oiio.geterror())
    return
spec = inp.spec()
xres = spec.width
yres = spec.height
nchannels = spec.nchannels

pixels = inp.read_image(0, 0, 0, nchannels, "uint8")
if pixels is None :
    print("Could not read pixels from", filename, ", error =", inp.geterror())
    return

if not inp.close() :
    print("Error closing", filename, ", error =", inp.geterror())
    return

```

4.3 ImageInput Class Reference

class **ImageInput**

ImageInput abstracts the reading of an image file in a file format-agnostic manner.

IOProxy aids for ImageInput implementations.

This set of utility functions are not meant to be called by user code. They are protected methods of *ImageInput*, and are used internally by the *ImageInput* implementation to help it properly implement support of IOProxy.

Creating an ImageInput

static *unique_ptr* **open**(const std::string &filename, const *ImageSpec* *config = nullptr, Filesystem::IOProxy *iopproxy = nullptr)

Create an *ImageInput* subclass instance that is able to read the given file and open it, returning a *unique_ptr* to the *ImageInput* if successful. The *unique_ptr* is set up with an appropriate deleter so the *ImageInput* will be properly closed and deleted when the *unique_ptr* goes out of scope or is reset. If the open fails, return an empty *unique_ptr* and set an error that can be retrieved by `OIIO::geterror()`.

The config, if not nullptr, points to an *ImageSpec* giving hints, requests, or special instructions. *ImageInput* implementations are free to not respond to any such requests, so the default implementation is just to ignore config.

open() will first try to make an *ImageInput* corresponding to the format implied by the file extension (for example, "foo.tif" will try the TIFF plugin), but if one is not found or if the inferred one does not open the file, every known *ImageInput* type will be tried until one is found that will open the file.

Parameters

- **filename** – The name of the file to open, UTF-8 encoded.
- **config** – Optional pointer to an *ImageSpec* whose metadata contains “configuration hints.”
- **ioproxy** – Optional pointer to an *IOProxy* to use (not supported by all formats, see `supports("ioproxy")`). The caller retains ownership of the proxy.

Returns

A `unique_ptr` that will close and free the *ImageInput* when it exits scope or is reset. The pointer will be empty if the required writer was not able to be created.

```
static inline unique_ptr open(const std::wstring &filename, const ImageSpec *config = nullptr,
                             Filesystem::IOProxy *ioproxy = nullptr)
```

Create and open an *ImageInput* using a UTF-16 encoded wstring filename.

```
static unique_ptr create(string_view filename, bool do_open = false, const ImageSpec *config = nullptr,
                        Filesystem::IOProxy *ioproxy = nullptr, string_view plugin_searchpath = "")
```

Create and return an *ImageInput* implementation that is able to read the given file or format. If `do_open` is true (and the `filename` is the name of a file, not just a format), fully open it if possible (using the optional `config` configuration spec, if supplied), otherwise just create the *ImageInput* but don't open it. The `plugin_searchpath` parameter is an override of the searchpath. colon-separated list of directories to search for ImageIO plugin DSO/DLL's (not a searchpath for the image itself!).

If the `filename` parameter is the name of a file format (such as “openexr”), it will create an *ImageInput* that reads that particular format. If the name is a file extension (such as “exr” or “.exr”), it will guess the file format from the extension and return that type of *ImageInput*.

If `filename` is a full file name (such as “hawaii.exr”), it will create an *ImageInput* that reads the format implied by the file extension (“.tif”) and try to open the file with that reader. If the file can be opened and appears to be of the correct type, then that *ImageInput* (after being closed) will be returned to the caller. But if it fails (say, because the file type does not match the extension), then every known kind of image reader will be tried in turn, until one can be found that succeeds in opening that file. The `create()` file will fail entirely only if no known image reader type succeeds.

If the caller intends to immediately open the file, then it is often simpler to call static *ImageInput::open()*.

Parameters

- **filename** – The name of an image file, or a file extension, or the name of a file format. The filename is UTF-8 encoded.
- **do_open** – If true, not only create but also open the file.
- **config** – Optional pointer to an *ImageSpec* whose metadata contains “configuration hints” for the *ImageInput* implementation.
- **ioproxy** – Optional pointer to an *IOProxy* to use (not supported by all formats, see `supports("ioproxy")`). The caller retains ownership of the proxy. If this is not supplied, it is still possible to set the proxy with a call to `set_proxy()` prior to `open()`.
- **plugin_searchpath** – An optional colon-separated list of directories to search for Open-ImageIO plugin DSO/DLL's.

Returns

A `unique_ptr` that will close and free the *ImageInput* when it exits scope or is reset. The pointer will be empty if the required writer was not able to be created.

```
static inline unique_ptr create(const std::wstring &filename, bool do_open = false, const ImageSpec *config  
                                = nullptr, Filesystem::IOProxy *ioprox = nullptr, string_view  
                                plugin_searchpath = "")
```

Create an *ImageInput* using a UTF-16 encoded wstring filename.

Reading pixels

Common features of all the read methods:

- The `format` parameter describes the data type of the `data[]` buffer. The read methods automatically convert the data from the data type it is stored in the file into the format of the data buffer. If `format` is `TypeUnknown` it will just copy pixels of file's native data layout (including, possibly, per-channel data formats as specified by the *ImageSpec*'s `channelformats` field).
- The `stride` values describe the layout of the data buffer: `xstride` is the distance in bytes between successive pixels within each scanline. `ystride` is the distance in bytes between successive scanlines. For volumetric images `zstride` is the distance in bytes between successive "volumetric planes". Strides set to the special value `AutoStride` imply contiguous data, i.e.,

```
xstride = format.size() * nchannels  
ystride = xstride * width  
zstride = ystride * height
```

- Any *range* parameters (such as `ybegin` and `yend`) describe a "half open interval", meaning that `begin` is the first item and `end` is *one past the last item*. That means that the number of items is `end - begin`.
- For ordinary 2D (non-volumetric) images, any `z` or `zbegin` coordinates should be 0 and any `zend` should be 1, indicating that only a single image "plane" exists.
- Some read methods take a channel range [`chbegin`,`chend`) to allow reading of a contiguous subset of channels (`chbegin`=0, `chend`=`spec.nchannels` reads all channels).
- *ImageInput* readers are expected to give the appearance of random access — in other words, if it can't randomly seek to the given scanline or tile, it should transparently close, reopen, and sequentially read through prior scanlines.
- All read functions return `true` for success, `false` for failure (after which a call to `geterror()` may retrieve a specific error message).

```
virtual bool read_scanline(int y, int z, TypeDesc format, void *data, stride_t xstride = AutoStride)
```

Read the scanline that includes pixels (*,y,z) from the "current" subimage and MIP level. The `xstride` value gives the distance between successive pixels (in bytes). Strides set to `AutoStride` imply "contiguous" data.

Note: This variety of `read_scanline` is not re-entrant nor thread-safe. If you require concurrent reads to the same open *ImageInput*, you should use `read_scanlines` that has the subimage and miplevel passed explicitly.

Parameters

- **y/z** – The y & z coordinates of the scanline. For 2D images, z should be 0.
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data buffer.
- **xstride** – The distance in bytes between successive pixels in data (or *AutoStride*).

Returns

true upon success, or false upon failure.

inline bool **read_scanline**(int y, int z, float *data)

Simple read_scanline reads into contiguous float pixels.

virtual bool **read_scanlines**(int subimage, int miplevel, int ybegin, int yend, int z, int chbegin, int chend, *TypeDesc* format, void *data, stride_t xstride = *AutoStride*, stride_t ystride = *AutoStride*)

Read multiple scanlines that include pixels (*,y,z) for all ybegin <= y < yend in the specified subimage and mip level, into data, using the strides given and converting to the requested data format (*TypeUnknown* indicates no conversion, just copy native data types). Only channels [chbegin, chend) will be read/copied (chbegin=0, chend=spec.nchannels reads all channels, yielding equivalent behavior to the simpler variant of read_scanlines).

This version of read_scanlines, because it passes explicit subimage/miplevel, does not require a separate call to seek_subimage, and is guaranteed to be thread-safe against other concurrent calls to any of the read_* methods that take an explicit subimage/miplevel (but not against any other *ImageInput* methods).

Note: This call was changed for OpenImageIO 2.0 to include the explicit subimage and miplevel parameters. The previous versions, which lacked subimage and miplevel parameters (thus were dependent on a prior call to seek_subimage) are considered deprecated.

Parameters

- **subimage** – The subimage to read from (starting with 0).
- **miplevel** – The MIP level to read (0 is the highest resolution level).
- **ybegin/yend** – The y range of the scanlines being passed.
- **z** – The z coordinate of the scanline.
- **chbegin/chend** – The channel range to read.
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.
- **xstride/ystride** – The distance in bytes between successive pixels and scanlines (or *AutoStride*).

Returns

true upon success, or false upon failure.

virtual bool **read_tile**(int x, int y, int z, *TypeDesc* format, void *data, stride_t xstride = *AutoStride*, stride_t ystride = *AutoStride*, stride_t zstride = *AutoStride*)

Read the tile whose upper-left origin is (x,y,z) into data[], converting if necessary from the native data format of the file into the format specified. The stride values give the data spacing of adjacent pixels, scanlines, and volumetric slices (measured in bytes). Strides set to *AutoStride* imply 'contiguous' data in the shape of a full tile, i.e.,

```
xstride = format.size() * spec.nchannels
ystride = xstride * spec.tile_width
zstride = ystride * spec.tile_height
```

Note: This variety of `read_tile` is not re-entrant nor thread-safe. If you require concurrent reads to the same open *ImageInput*, you should use `read_tiles()` that has the subimage and miplevel passed explicitly.

Note: This call will fail if the image is not tiled, or if (x,y,z) is not the upper left corner coordinates of a tile.

Parameters

- **x/y/z** – The upper left coordinate of the tile being passed.
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.
- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes (or `AutoStride` to indicate a “contiguous” single tile).

Returns

true upon success, or false upon failure.

inline bool **read_tile**(int x, int y, int z, float *data)

Simple `read_tile` reads into contiguous float pixels.

virtual bool **read_tiles**(int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, *TypeDesc* format, void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

Read the block of multiple tiles that include all pixels in

```
[xbegin,xend) X [ybegin,yend) X [zbegin,zend)
```

This is analogous to calling `read_tile(x,y,z,...)` for each tile in turn (but for some file formats, reading multiple tiles may allow it to read more efficiently or in parallel).

The begin/end pairs must correctly delineate tile boundaries, with the exception that it may also be the end of the image data if the image resolution is not a whole multiple of the tile size. The stride values give the data spacing of adjacent pixels, scanlines, and volumetric slices (measured in bytes). Strides set to `AutoStride` imply contiguous data in the shape of the [begin,end) region, i.e.,

```
xstride = format.size() * spec.nchannels
ystride = xstride * (xend-xbegin)
zstride = ystride * (yend-ybegin)
```

This version of `read_tiles`, because it passes explicit subimage and miplevel, does not require a separate call to `seek_subimage`, and is guaranteed to be thread-safe against other concurrent calls to any of the `read_*` methods that take an explicit subimage/miplevel (but not against any other *ImageInput* methods).

Note: The call will fail if the image is not tiled, or if the pixel ranges do not fall along tile (or image) boundaries, or if it is not a valid tile range.

Parameters

- **subimage** – The subimage to read from (starting with 0).
- **miplevel** – The MIP level to read (0 is the highest resolution level).
- **xbegin/xend** – The x range of the pixels covered by the group of tiles being read.
- **ybegin/yend** – The y range of the pixels covered by the tiles.
- **zbegin/zend** – The z range of the pixels covered by the tiles (for a 2D image, zbegin=0 and zend=1).
- **chbegin/chend** – The channel range to read.
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.
- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes (or *AutoStride*).

Returns

true upon success, or false upon failure.

```
virtual bool read_image(int subimage, int miplevel, int chbegin, int chend, TypeDesc format, void *data,
    stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride =
    AutoStride, ProgressCallback progress_callback = NULL, void
    *progress_callback_data = NULL)
```

Read the entire image of `spec.width` x `spec.height` x `spec.depth` pixels into a buffer with the given strides and in the desired data format.

Depending on the spec, this will read either all tiles or all scanlines. Assume that data points to a layout in row-major order.

This version of `read_image`, because it passes explicit subimage and miplevel, does not require a separate call to `seek_subimage`, and is guaranteed to be thread-safe against other concurrent calls to any of the `read_*` methods that take an explicit subimage/miplevel (but not against any other *ImageInput* methods).

Because this may be an expensive operation, a progress callback may be passed. Periodically, it will be called as follows:

```
progress_callback (progress_callback_data, float done);
```

where `done` gives the portion of the image (between 0.0 and 1.0) that has been written thus far.

Parameters

- **subimage** – The subimage to read from (starting with 0).
- **miplevel** – The MIP level to read (0 is the highest resolution level).
- **chbegin/chend** – The channel range to read. If `chend` is -1, it will be set to `spec.nchannels`.
- **format** – A *TypeDesc* describing the type of data.
- **data** – Pointer to the pixel data.

- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes (or AutoStride).
- **progress_callback/progress_callback_data** – Optional progress callback.

Returns

true upon success, or false upon failure.

virtual bool **read_native_deep_scanlines**(int subimage, int miplevel, int ybegin, int yend, int z, int chbegin, int chend, *DeepData* &deepdata)

Read deep scanlines containing pixels (*,y,z), for all y in the range [ybegin,yend) into deepdata. This will fail if it is not a deep file.

Parameters

- **subimage** – The subimage to read from (starting with 0).
- **miplevel** – The MIP level to read (0 is the highest resolution level).
- **chbegin/chend** – The channel range to read.
- **ybegin/yend** – The y range of the scanlines being passed.
- **z** – The z coordinate of the scanline.
- **deepdata** – A *DeepData* object into which the data for these scanlines will be placed.

Returns

true upon success, or false upon failure.

virtual bool **read_native_deep_tiles**(int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, *DeepData* &deepdata)

Read into deepdata the block of native deep data tiles that include all pixels and channels specified by pixel range.

Note: The call will fail if the image is not tiled, or if the pixel ranges do not fall along tile (or image) boundaries, or if it is not a valid tile range.

Parameters

- **subimage** – The subimage to read from (starting with 0).
- **miplevel** – The MIP level to read (0 is the highest resolution level).
- **xbegin/xend** – The x range of the pixels covered by the group of tiles being read.
- **ybegin/yend** – The y range of the pixels covered by the tiles.
- **zbegin/zend** – The z range of the pixels covered by the tiles (for a 2D image, zbegin=0 and zend=1).
- **chbegin/chend** – The channel range to read.
- **deepdata** – A *DeepData* object into which the data for these tiles will be placed.

Returns

true upon success, or false upon failure.

virtual bool **read_native_deep_image**(int subimage, int miplevel, *DeepData* &deepdata)

Read the entire deep data image of spec.width x spec.height x spec.depth pixels, all channels, into deepdata.

Parameters

- **subimage** – The subimage to read from (starting with 0).
- **miplevel** – The MIP level to read (0 is the highest resolution level).
- **deepdata** – A *DeepData* object into which the data for the image will be placed.

Returns

true upon success, or false upon failure.

Reading native pixels – implementation overloads

Note: `read_native_*` methods are usually not directly called by user code (except for `read_native_deep_*` varieties). These are the methods that are overloaded by the *ImageInput* subclasses that implement the individual file format readers.

virtual bool **read_native_scanline**(int subimage, int miplevel, int y, int z, void *data) = 0

Read a single scanline (all channels) of native data into contiguous memory.

virtual bool **read_native_scanlines**(int subimage, int miplevel, int ybegin, int yend, int z, void *data)

Read a range of scanlines (all channels) of native data into contiguous memory.

virtual bool **read_native_scanlines**(int subimage, int miplevel, int ybegin, int yend, int z, int chbegin, int chend, void *data)

Read a range of scanlines (with optionally a subset of channels) of native data into contiguous memory.

virtual bool **read_native_tile**(int subimage, int miplevel, int x, int y, int z, void *data)

Read a single tile (all channels) of native data into contiguous memory. The base class `read_native_tile` fails. A format reader that supports tiles **MUST** overload this virtual method that reads a single tile (all channels).

virtual bool **read_native_tiles**(int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, void *data)

Read multiple tiles (all channels) of native data into contiguous memory. A format reader that supports reading multiple tiles at once (in a way that's more efficient than reading the tiles one at a time) is advised (but not required) to overload this virtual method. If an *ImageInput* subclass does not overload this, the default implementation here is simply to loop over the tiles, calling the single-tile `read_native_tile()` for each one.

virtual bool **read_native_tiles**(int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, void *data)

Read multiple tiles (potentially a subset of channels) of native data into contiguous memory. A format reader that supports reading multiple tiles at once, and can handle a channel subset while doing so, is advised (but not required) to overload this virtual method. If an *ImageInput* subclass does not overload this, the default implementation here is simply to loop over the tiles, calling the single-tile `read_native_tile()` for each one (and copying carefully to handle the channel subset issues).

Public Types

using **unique_ptr** = std::unique_ptr<*ImageInput*>
unique_ptr to an *ImageInput*

typedef std::lock_guard<const *ImageInput*&> **lock_guard**

The presence of *lock()* and *unlock()* establish an *ImageInput* itself as having the BasicLockable concept and therefore can be used by std::lock_guard.

typedef *ImageInput* *(***Creator**)()

Call signature of a function that creates and returns an *ImageInput**.

Public Functions

virtual const char ***format_name**(void) const = 0

Return the name of the format implemented by this class.

inline virtual int **supports**(string_view feature) const

Given the name of a “feature”, return whether this *ImageInput* supports output of images with the given properties. Most queries will simply return 0 for “doesn’t support” and 1 for “supports it,” but it is acceptable to have queries return other nonzero integers to indicate varying degrees of support or limits (but should be clearly documented as such).

Feature names that *ImageInput* implementations are expected to recognize include:

- "arbitrary_metadata" : Does this format allow metadata with arbitrary names and types?
- "exif" : Can this format store Exif camera data?
- "ioproxy" : Does this format reader support reading from an IOProxy?
- "iptc" : Can this format store IPTC data?
- "procedural" : Can this format create images without reading from a disk file?
- "thumbnail" : Does this format reader support retrieving a reduced resolution copy of the image via the *thumbnail()* method?
 - "multiimage" : Does this format support multiple subimages within a file? (Note: this doesn’t necessarily mean that the particular file this *ImageInput* is reading has multiple subimages.)
 - "noimage" : Does this format allow 0x0 sized images, i.e. an image file with metadata only and no pixels?

This list of queries may be extended in future releases. Since this can be done simply by recognizing new query strings, and does not require any new API entry points, addition of support for new queries does not break ‘link compatibility’ with previously-compiled plugins.

virtual bool **valid_file**(const std::string &filename) const

Return true if the *filename* names a file of the type for this *ImageInput*. The implementation will try to determine this as efficiently as possible, in most cases much less expensively than doing a full *open()*. Note that there can be false positives: a file can appear to be of the right type (i.e., *valid_file()* returning true) but still fail a subsequent call to *open()*, such as if the contents of the file are truncated, nonsensical, or otherwise corrupted. The filename is UTF-8 encoded.

Returns

true upon success, or false upon failure.

inline bool **valid_file**(const std::wstring &filename) const

Check valid file using a UTF-16 encoded wstring filename.

virtual bool **valid_file**(Filesystem::IOProxy *ioproxy) const

Return true if the *ioproxy* represents a file of the type for this *ImageInput*. The implementation will try to determine this as efficiently as possible, in most cases much less expensively than doing a full *open()*. Note that there can be false positives: a file can appear to be of the right type (i.e., *valid_file()* returning true) but still fail a subsequent call to *open()*, such as if the contents of the file are truncated, nonsensical, or otherwise corrupted.

Returns

true upon success, or false upon failure.

virtual bool **open**(const std::string &name, *ImageSpec* &newspec) = 0

Opens the file with given name and seek to the first subimage in the file. Various file attributes are put in *newspec* and a copy is also saved internally to the *ImageInput* (retrievable via *spec()*). From examining *newspec* or *spec()*, you can discern the resolution, if it's tiled, number of channels, native data format, and other metadata about the image.

Parameters

- **name** – Filename to open, UTF-8 encoded.
- **newspec** – Reference to an *ImageSpec* in which to deposit a full description of the contents of the first subimage of the file.

Returns

true if the file was found and opened successfully.

inline bool **open**(const std::wstring &name, *ImageSpec* &newspec)

Open the *ImageInput* using a UTF-16 encoded wstring filename.

inline virtual bool **open**(const std::string &name, *ImageSpec* &newspec, const *ImageSpec* &config)

Open file with given name, similar to *open(name, newspec)*. The *config* is an *ImageSpec* giving requests or special instructions. *ImageInput* implementations are free to not respond to any such requests, so the default implementation is just to ignore *config* and call regular *open(name, newspec)*.

Parameters

- **name** – Filename to open, UTF-8 encoded.
- **newspec** – Reference to an *ImageSpec* in which to deposit a full description of the contents of the first subimage of the file.
- **config** – An *ImageSpec* whose metadata contains “configuration hints” for the *ImageInput* implementation.

Returns

true if the file was found and opened successfully.

inline bool **open**(const std::wstring &name, *ImageSpec* &newspec, const *ImageSpec* &config)

Open the *ImageInput* using a UTF-16 encoded wstring filename.

inline virtual const *ImageSpec* &**spec**(void) const

Return a reference to the image specification of the current subimage/MIPlevel. Note that the contents of the *spec* are invalid before *open()* or after *close()*, and may change with a call to *seek_subimage()*. It is thus not thread-safe, since the *spec* may change if another thread calls *seek_subimage*, or any of the *read_*()* functions that take explicit subimage/miplevel.

virtual *ImageSpec* **spec**(int subimage, int miplevel = 0)

Return a full copy of the *ImageSpec* of the designated subimage and MIPlevel. This method is thread-safe, but it is potentially expensive, due to the work that needs to be done to fully copy an *ImageSpec* if there is lots of named metadata to allocate and copy. See also the less expensive *spec_dimensions()*. Errors (such as having requested a nonexistent subimage) are indicated by returning an *ImageSpec* with `format==TypeUnknown`.

virtual *ImageSpec* **spec_dimensions**(int subimage, int miplevel = 0)

Return a copy of the *ImageSpec* of the designated subimage and miplevel, but only the dimension and type fields. Just as with a call to *ImageSpec::copy_dimensions()*, neither the channel names nor any of the arbitrary named metadata will be copied, thus this is a relatively inexpensive operation if you don't need that information. It is guaranteed to be thread-safe. Errors (such as having requested a nonexistent subimage) are indicated by returning an *ImageSpec* with `format==TypeUnknown`.

inline virtual bool **get_thumbnail**(ImageBuf &thumb, int subimage)

Retrieve a reduced-resolution ("thumbnail") version of the given subimage. It is guaranteed to be thread-safe.

Note: This method was added to OpenImageIO 2.3.

Parameters

- **thumb** – A reference to an *ImageBuf* which will be overwritten with the thumbnail image.
- **subimage** – The index of the subimage in the file whose thumbnail is to be retrieved.

Returns

true upon success, false if no thumbnail was available, or if this file format (or reader) does not support thumbnails.

virtual bool **close**() = 0

Close an open *ImageInput*. The call to *close()* is not strictly necessary if the *ImageInput* is destroyed immediately afterwards, since it is required for the destructor to close if the file is still open.

Returns

true upon success, or false upon failure.

inline virtual int **current_subimage**(void) const

Returns the index of the subimage that is currently being read. The first subimage (or the only subimage, if there is just one) is number 0.

inline virtual int **current_miplevel**(void) const

Returns the index of the MIPmap image that is currently being read. The highest-res MIP level (or the only level, if there is just one) is number 0.

inline virtual bool **seek_subimage**(int subimage, int miplevel)

Seek to the given subimage and MIP-map level within the open image file. The first subimage of the file has index 0, the highest-resolution MIP level has index 0. The new subimage's vital statistics may be retrieved by `this->spec()`. The reader is expected to give the appearance of random access to subimages and MIP levels; in other words, if it can't randomly seek to the given subimage/level, it should transparently close, reopen, and sequentially read through prior subimages and levels.

Returns

true upon success, or false upon failure. A failure may indicate that no such subimage or MIP level exists in the file.

virtual bool **set_ioproxy**(Filesystem::IOProxy *ioprox)

Set an IOProxy for this reader. This must be called prior to *open()*, and only for readers that support them (*supports("ioproxy")*). The caller retains ownership of the proxy.

Returns

true for success, false for failure.

bool **has_error**() const

Is there a pending error message waiting to be retrieved, that resulted from an *ImageInput* API call made by the this thread?

Note that any *error()* calls issued are thread-specific, and the *geterror()/has_error()* are expected to be called by the same thread that called whichever API function encountered an error.

std::string **geterror**(bool clear = true) const

Return the text of all pending error messages issued against this *ImageInput* by the calling thread, and clear the pending error message unless *clear* is false. If no error message is pending, it will return an empty string.

Note that any *error()* calls issued are thread-specific, and the *geterror()/has_error()* are expected to be called by the same thread that called whichever API function encountered an error.

template<typename ...**Args**>

inline void **errorfmt**(const char *fmt, const *Args*&... args) const

Error reporting for the plugin implementation: call this with std::format-like arguments. It is not necessary to have the error message contain a trailing newline.

void **threads**(int n)

Set the threading policy for this *ImageInput*, controlling the maximum amount of parallelizing thread “fan-out” that might occur during large read operations. The default of 0 means that the global attribute(“threads”) value should be used (which itself defaults to using as many threads as cores; see Section Global Attributes_).

The main reason to change this value is to set it to 1 to indicate that the calling thread should do all the work rather than spawning new threads. That is probably the desired behavior in situations where the calling application has already spawned multiple worker threads.

int **threads**() const

Retrieve the current thread-spawning policy.

See also:

threads(int)

void **lock**() const

There is a (hidden) internal recursive mutex to each *ImageInput* that can be used by the II to enforce thread safety. This is exposed via the obvious *lock()/unlock()/try_lock()* semantics.

virtual size_t **heapsize**() const

Memory tracking method. Return the total heap memory allocated by *ImageInput*. Overridable version of heapsize defined in memory.h.

virtual size_t **footprint**() const

Memory tracking method. Return the total memory footprint of *ImageInput*. Overridable version of footprint defined in memory.h.

WRITING IMAGEIO PLUGINS

5.1 Plugin Introduction

As explained in Chapters *ImageInput: Reading Images* and *ImageOutput: Writing Images*, the ImageIO library does not know how to read or write any particular image formats, but rather relies on plugins located and loaded dynamically at run-time. This set of plugins, and therefore the set of image file formats that OpenImageIO or its clients can read and write, is extensible without needing to modify OpenImageIO itself.

This chapter explains how to write your own OpenImageIO plugins. We will first explain separately how to write image file readers and writers, then tie up the loose ends of how to build the plugins themselves.

5.2 Image Reader Plugins

A plugin that reads a particular image file format must implement a *subclass* of ImageInput (described in Chapter *ImageInput: Reading Images*). This is actually very straightforward and consists of the following steps, which we will illustrate with a real-world example of writing a JPEG/JFIF plug-in.

1. Read the base class definition from `imageio.h`. It may also be helpful to enclose the contents of your plugin in the same namespace that the OpenImageIO library uses:

```
#include <OpenImageIO/imageio.h>
OIIO_PLUGIN_NAMESPACE_BEGIN

// ... everything else ...

OIIO_PLUGIN_NAMESPACE_END
```

2. Declare these public items:
 - a. An integer called `name_imageio_version` that identifies the version of the ImageIO protocol implemented by the plugin, defined in `imageio.h` as the constant `OIIO_PLUGIN_VERSION`. This allows the library to be sure it is not loading a plugin that was compiled against an incompatible version of OpenImageIO.
 - b. An function named `name_imageio_library_version` that identifies the underlying dependent library that is responsible for reading or writing the format (it may return `nullptr` to indicate that there is no dependent library being used for this format).
 - c. A function named `name_input_imageio_create` that takes no arguments and returns an `ImageInput *` constructed from a new instance of your ImageInput subclass and a deleter. (Note that *name* is the name of your format, and must match the name of the plugin itself.)

- d. An array of `char *` called `name_input_extensions` that contains the list of file extensions that are likely to indicate a file of the right format. The list is terminated by a `nullptr`.

All of these items must be inside an `extern "C"` block in order to avoid name mangling by the C++ compiler, and we provide handy macros `OIIO_PLUGIN_EXPORTS_BEGIN` and `OIIO_PLUGIN_EXPORTS_END` to make this easy. Depending on your compiler, you may need to use special commands to dictate that the symbols will be exported in the DSO; we provide a special `OIIO_EXPORT` macro for this purpose, defined in `export.h`.

Putting this all together, we get the following for our JPEG example:

```
OIIO_PLUGIN_EXPORTS_BEGIN
    OIIO_EXPORT int jpeg_imageio_version = OIIO_PLUGIN_VERSION;
    OIIO_EXPORT ImageInput *jpeg_input_imageio_create () {
        return new JpgInput;
    }
    OIIO_EXPORT const char *jpeg_input_extensions[] = {
        "jpg", "jpe", "jpeg", "jif", "jfif", "jfi", nullptr
    };
    OIIO_EXPORT const char* jpeg_imageio_library_version () {
        #define STRINGIZE2(a) #a
        #define STRINGIZE(a) STRINGIZE2(a)
        #ifdef LIBJPEG_TURBO_VERSION
            return "jpeg-turbo " STRINGIZE(LIBJPEG_TURBO_VERSION);
        #else
            return "jpeglib " STRINGIZE(JPEG_LIB_VERSION_MAJOR) "."
                STRINGIZE(JPEG_LIB_VERSION_MINOR);
        #endif
    }
OIIO_PLUGIN_EXPORTS_END
```

3. The definition and implementation of an `ImageInput` subclass for this file format. It must publicly inherit `ImageInput`, and must overload the following methods which are “pure virtual” in the `ImageInput` base class:
 - a. `format_name()` should return the name of the format, which ought to match the name of the plugin and by convention is strictly lower-case and contains no whitespace.
 - b. `open()` should open the file and return true, or should return false if unable to do so (including if the file was found but turned out not to be in the format that your plugin is trying to implement).
 - c. `close()` should close the file, if open.
 - d. `read_native_scanline()` should read a single scanline from the file into the address provided, uncompressing it but keeping it in its naive data format without any translation.
 - e. The virtual destructor, which should `close()` if the file is still open, addition to performing any other tear-down activities.

Additionally, your `ImageInput` subclass may optionally choose to overload any of the following methods, which are defined in the `ImageInput` base class and only need to be overloaded if the default behavior is not appropriate for your plugin:

- f. `supports()`, only if your format supports any of the optional features described in the section describing `ImageInput::supports`.
- g. `valid_file()`, if your format has a way to determine if a file is of the given format in a way that is less expensive than a full `open()`.
- h. `seek_subimage()`, only if your format supports reading multiple subimages within a single file.

- i. `read_native_scanlines()`, only if your format has a speed advantage when reading multiple scanlines at once. If you do not supply this function, the default implementation will simply call `read_scanline()` for each scanline in the range.
- j. `read_native_tile()`, only if your format supports reading tiled images.
- k. `read_native_tiles()`, only if your format supports reading tiled images and there is a speed advantage when reading multiple tiles at once. If you do not supply this function, the default implementation will simply call `read_native_tile()` for each tile in the range.
- l. Channel subset'' versions of `read_native_scanlines()` and/or `read_native_tiles()`, only if your format has a more efficient means of reading a subset of channels. If you do not supply these methods, the default implementation will simply use `read_native_scanlines()` or `read_native_tiles()` to read into a temporary all-channel buffer and then copy the channel subset into the user's buffer.
- m. `read_native_deep_scanlines()` and/or `read_native_deep_tiles()`, only if your format supports "deep" data images.

Here is how the class definition looks for our JPEG example. Note that the JPEG/JFIF file format does not support multiple subimages or tiled images.

```
class JpgInput final : public ImageInput {
public:
    JpgInput () { init(); }
    ~JpgInput () override { close(); }
    const char * format_name (void) const override { return "jpeg"; }
    bool open (const std::string &name, ImageSpec &spec) override;
    bool read_native_scanline (int y, int z, void *data) override;
    bool close () override;
private:
    FILE *m_fd;
    bool m_first_scanline;
    struct jpeg_decompress_struct m_cinfo;
    struct jpeg_error_mgr m_jerr;

    void init () { m_fd = NULL; }
};
```

Your subclass implementation of `open()`, `close()`, and `read_native_scanline()` are the heart of an `ImageInput` implementation. (Also `read_native_tile()` and `seek_subimage()`, for those image formats that support them.)

The remainder of this section simply lists the full implementation of our JPEG reader, which relies heavily on the open source `jpeg-6b` library to perform the actual JPEG decoding.

5.3 Image Writers

A plugin that writes a particular image file format must implement a *subclass* of `ImageOutput` (described in Chapter *ImageOutput: Writing Images*). This is actually very straightforward and consists of the following steps, which we will illustrate with a real-world example of writing a JPEG/JFIF plug-in.

1. Read the base class definition from `imageio.h`, just as with an image reader (see Section *Image Reader Plugins*).
2. Declare four public items:
 - a. An integer called `name_imageio_version` that identifies the version of the ImageIO protocol implemented by the plugin, defined in `imageio.h` as the constant `OIIO_PLUGIN_VERSION`. This allows the library to be sure it is not loading a plugin that was compiled against an incompatible version of OpenImageIO. Note that if your plugin has both a reader and writer and they are compiled as separate modules (C++ source files), you don't want to declare this in *both* modules; either one is fine.
 - b. A function named `name_output_imageio_create` that takes no arguments and returns an `ImageOutput` * constructed from a new instance of your `ImageOutput` subclass and a deleter. (Note that *name* is the name of your format, and must match the name of the plugin itself.)
 - c. An array of `char *` called `name_output_extensions` that contains the list of file extensions that are likely to indicate a file of the right format. The list is terminated by a `nullptr` pointer.

All of these items must be inside an `extern "C"` block in order to avoid name mangling by the C++ compiler, and we provide handy macros `OIIO_PLUGIN_EXPORTS_BEGIN` and `OIIO_PLUGIN_EXPORTS_END` to make this easy. Depending on your compiler, you may need to use special commands to dictate that the symbols will be exported in the DSO; we provide a special `OIIO_EXPORT` macro for this purpose, defined in `export.h`.

Putting this all together, we get the following for our JPEG example:

```

OIIO_PLUGIN_EXPORTS_BEGIN
    OIIO_EXPORT int jpeg_imageio_version = OIIO_PLUGIN_VERSION;
    OIIO_EXPORT ImageOutput *jpeg_output_imageio_create () {
        return new JpgOutput;
    }
    OIIO_EXPORT const char *jpeg_input_extensions[] = {
        "jpg", "jpe", "jpeg", nullptr
    };
OIIO_PLUGIN_EXPORTS_END

```

3. The definition and implementation of an `ImageOutput` subclass for this file format. It must publicly inherit `ImageOutput`, and must overload the following methods which are “pure virtual” in the `ImageOutput` base class:
 - a. `format_name()` should return the name of the format, which ought to match the name of the plugin and by convention is strictly lower-case and contains no whitespace.
 - b. `supports()` should return `true` if its argument names a feature supported by your format plugin, `false` if it names a feature not supported by your plugin. See the description of `ImageOutput::supports()` for the list of feature names.

- c. `open()` should open the file and return true, or should return false if unable to do so (including if the file was found but turned out not to be in the format that your plugin is trying to implement).
- d. `close()` should close the file, if open.
- e. `write_scanline()` should write a single scanline to the file, translating from internal to native data format and handling strides properly.
- f. The virtual destructor, which should `close()` if the file is still open, addition to performing any other tear-down activities.

Additionally, your `ImageOutput` subclass may optionally choose to overload any of the following methods, which are defined in the `ImageOutput` base class and only need to be overloaded if the default behavior is not appropriate for your plugin:

- g. `write_scanlines()`, only if your format supports writing scanlines and you can get a performance improvement when outputting multiple scanlines at once. If you don't supply `write_scanlines()`, the default implementation will simply call `write_scanline()` separately for each scanline in the range.
- h. `write_tile()`, only if your format supports writing tiled images.
- i. `write_tiles()`, only if your format supports writing tiled images and you can get a performance improvement when outputting multiple tiles at once. If you don't supply `write_tiles()`, the default implementation will simply call `write_tile()` separately for each tile in the range.
- j. `write_rectangle()`, only if your format supports writing arbitrary rectangles.
- k. `write_image()`, only if you have a more clever method of doing so than the default implementation that calls `write_scanline()` or `write_tile()` repeatedly.
- l. `write_deep_scanlines()` and/or `write_deep_tiles()`, only if your format supports "deep" data images.

It is not strictly required, but certainly appreciated, if a file format does not support tiles, to nonetheless accept an `ImageSpec` that specifies tile sizes by allocating a full-image buffer in `open()`, providing an implementation of `write_tile()` that copies the tile of data to the right spots in the buffer, and having `close()` then call `write_scanlines()` to process the buffer now that the image has been fully sent.

Here is how the class definition looks for our JPEG example. Note that the JPEG/JFIF file format does not support multiple subimages or tiled images.

```
class JpgOutput final : public ImageOutput {
public:
    JpgOutput () { init(); }
    ~JpgOutput () override { close(); }
    const char * format_name (void) const override { return "jpeg"; }
    int supports (string_view property) const override { return false; }
    bool open (const std::string &name, const ImageSpec &spec,
               bool append=false) override;
    bool write_scanline (int y, int z, TypeDesc format,
                        const void *data, stride_t xstride) override;
    bool close ();
private:
    FILE *m_fd;
    std::vector<unsigned char> m_scratch;
    struct jpeg_compress_struct m_cinfo;
    struct jpeg_error_mgr m_jerr;

    void init () { m_fd = NULL; }
};
```

Your subclass implementation of `open()`, `close()`, and `write_scanline()` are the heart of an `ImageOutput` implementation. (Also `write_tile()`, for those image formats that support tiled output.)

An `ImageOutput` implementation must properly handle all data formats and strides passed to `write_scanline()` or `write_tile()`, unlike an `ImageInput` implementation, which only needs to read scanlines or tiles in their native format and then have the super-class handle the translation. But don't worry, all the heavy lifting can be accomplished with the following helper functions provided as protected member functions of `ImageOutput` that convert a scanline, tile, or rectangular array of values from one format to the native format(s) of the file.

```
const void *to_native_scanline(TypeDesc format, const void *data, stride_t xstride, std::vector<unsigned char>
                               &scratch, unsigned int dither = 0, int yorigin = 0, int zorigin = 0)
```

Convert a full scanline of pixels (pointed to by `data` with the given `format` and `strides` into contiguous pixels in the native format (described by the `ImageSpec` returned by the `spec()` member function). The location of the newly converted data is returned, which may either be the original `data` itself if no data conversion was necessary and the requested layout was contiguous (thereby avoiding unnecessary memory copies), or may point into memory allocated within the `scratch` vector passed by the user. In either case, the caller doesn't need to worry about thread safety or freeing any allocated memory (other than eventually destroying the `scratch` vector).

```
const void *to_native_tile(TypeDesc format, const void *data, stride_t xstride, stride_t ystride, stride_t zstride,
                           std::vector<unsigned char> &scratch, unsigned int dither = 0, int xorigin = 0, int
                           yorigin = 0, int zorigin = 0)
```

Convert a full tile of pixels (pointed to by `data` with the given `format` and `strides` into contiguous pixels in the native format (described by the `ImageSpec` returned by the `spec()` member function). The location of the newly converted data is returned, which may either be the original `data` itself if no data conversion was necessary and the requested layout was contiguous (thereby avoiding unnecessary memory copies), or may point into memory allocated within the `scratch` vector passed by the user. In either case, the caller doesn't need to worry about thread safety or freeing any allocated memory (other than eventually destroying the `scratch` vector).

```
const void *to_native_rectangle(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, TypeDesc format,
                                const void *data, stride_t xstride, stride_t ystride, stride_t zstride,
                                std::vector<unsigned char> &scratch, unsigned int dither = 0, int xorigin = 0,
                                int yorigin = 0, int zorigin = 0)
```

Convert a rectangle of pixels (pointed to by `data` with the given `format`, dimensions, and `strides` into contiguous pixels in the native format (described by the `ImageSpec` returned by the `spec()` member function). The location of the newly converted data is returned, which may either be the original `data` itself if no data conversion was necessary and the requested layout was contiguous (thereby avoiding unnecessary memory copies), or may point into memory allocated within the `scratch` vector passed by the user. In either case, the caller doesn't need to worry about thread safety or freeing any allocated memory (other than eventually destroying the `scratch` vector).

For float to 8 bit integer conversions only, if `dither` parameter is nonzero, random dither will be added to reduce quantization banding artifacts; in this case, the specific nonzero `dither` value is used as a seed for the hash function that produces the per-pixel dither amounts, and the optional `origin` parameters help it to align the pixels to the right position in the dither pattern.

The remainder of this section simply lists the full implementation of our JPEG writer, which relies heavily on the open source `jpeg-6b` library to perform the actual JPEG encoding.

5.4 Tips and Conventions

OpenImageIO's main goal is to hide all the pesky details of individual file formats from the client application. This inevitably leads to various mismatches between a file format's true capabilities and requests that may be made through the OpenImageIO APIs. This section outlines conventions, tips, and rules of thumb that we recommend for image file support.

Readers

- If the file format stores images in a non-spectral color space (for example, YUV), the reader should automatically convert to RGB to pass through the OIIO APIs. In such a case, the reader should signal the file's true color space via a "Foo:colorspace" attribute in the ImageSpec.
- "Palette" images should be automatically converted by the reader to RGB.
- If the file supports thumbnail images in its header, the reader should provide an `ImageInput::get_thumbnail()` method, as well as store the thumbnail dimensions in the ImageSpec as attributes "thumbnail_width", "thumbnail_height", and "thumbnail_nchannels" (all of which should be int).

Writers

The overall rule of thumb is: try to always "succeed" at writing the file, outputting the closest approximation of the user's data as possible. But it is permissible to fail the `open()` call if it is clearly nonsensical or there is no possible way to output a decent approximation of the user's data. Some tips:

- If the client application requests a data format not directly supported by the file type, silently write the supported data format that will result in the least precision or range loss.
- It is customary to fail a call to `open()` if the ImageSpec requested a number of color channels plainly not supported by the file format. As an exception to this rule, it is permissible for a file format that does not support alpha channels to silently drop the fourth (alpha) channel of a 4-channel output request.
- If the app requests a "Compression" not supported by the file format, you may choose as a default any lossless compression supported. Do not use a lossy compression unless you are fairly certain that the app wanted a lossy compression.
- If the file format is able to store images in a non-spectral color space (for example, YUV), the writer may accept a "Foo:colorspace" attribute in the ImageSpec as a request to automatically convert and store the data in that format (but it will always be passed as RGB through the OIIO APIs).

- If the file format can support thumbnail images in its header, and the ImageSpec contain attributes "thumbnail_width", "thumbnail_height", "thumbnail_nchannels", and "thumbnail_image", the writer should attempt to store the thumbnail if possible.

BUNDLED IMAGEIO PLUGINS

This chapter lists all the image format plugins that are bundled with OpenImageIO. For each plugin, we delineate any limitations, custom attributes, etc. The plugins are listed alphabetically by format name.

6.1 BMP

BMP is a bitmap image file format used mostly on Windows systems. BMP files use the file extension `.bmp`.

BMP is not a nice format for high-quality or high-performance images. It only supports unsigned integer 1-, 2-, 4-, and 8- bits per channel; only grayscale, RGB, and RGBA; does not support MIPmaps, multiimage, or tiles.

BMP Attributes

ImageSpec Attribute	Type	BMP header data or explanation
compression	string	The compression of the BMP file ("rle4" or "rle8", if RLE compression is used).
XResolution	float	hres
YResolution	float	vres
ResolutionUnit	string	always "m" (pixels per meter)
bmp:bitsperpixel	int	When not a whole number of bytes per channel, this describes the bits per pixel in the file (16 for R4G4B4, 8 for a 256-color palette image, 4 for a 16-color palette image, 1 for a 2-color palette image).
bmp:version	int	Version of the BMP file format
oiio:ColorSpace	string	currently, it is always "sRGB" (we presume all BMP files are sRGB)

Configuration settings for BMP input

When opening a BMP ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
bmp:monochrome_detect	int	If nonzero, try to detect when all palette entries are gray and pretend that it's a 1-channel image to allow the calling app to save memory and time (even though the BMP format does not actually support grayscale images per se. It is 1 by default, but by setting the hint to 0, you can disable this behavior.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for BMP output

When opening an BMP ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to a memory buffer.
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.

Custom I/O Overrides

BMP input and output both support the “custom I/O” feature via the special “oiio:ioproxy” attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

BMP Limitations

- OIIO’s current implementation will only write uncompressed 8bpp (from a 1-channel source), 24bpp (if 3 channel), or 32bpp (if 4 channel). Reads, however, can handle RLE compression as well as 1, 4, or 16 bpp input.
- Only 1, 3, and 4-channel images are supported with BMP due to limitations of the file format itself.
- BMP only supports uint8 pixel data types. Requests for other pixel data types will automatically be converted to uint8.
- OIIO’s current implementation only supports RGB BMP files and presumes that the pixel data are in sRGB color space. It does not currently support CMYK files or the color primary header information. (Though if this is important to anyone, support can be added in the future.)

6.2 Cineon

Cineon is an image file format developed by Kodak that is commonly used for scanned motion picture film and digital intermediates. Cineon files use the file extension `.cin`.

6.3 DDS

DDS (Direct Draw Surface) is an image file format designed by Microsoft for use in Direct3D graphics. DDS files use the extension `.dds`.

DDS is primarily meant for images that are directly usable by the GPU. It supports 2D, cube and volume images with or without MIPmaps; using either uncompressed pixel formats or one of the lossy compression schemes supported by the graphics hardware (BC1-BC7).

OpenImageIO currently only supports reading DDS files, not writing them.

DDS files containing a “normal map” (`0x80000000`) pixel format flag will be interpreted as a tangent space normal map. When reading such files, the resulting image will be a 3-channel image with red & green channels coming from file data, and the blue channel computed as if it were the Z component of a normal map. This applies to images using DXT5 compression (normal X & Y components are assumed to be in alpha & green channels) and images using BC5/ATI2 compression (normal X & Y components are in red & green channels).

Attributes

ImageSpec Attribute	Type	DDS header data or explanation
<code>compression</code>	string	Compression type
<code>oiio:BitsPerSample</code>	int	bits per sample
<code>textureformat</code>	string	Set correctly to one of "Plain Texture", "Volume Texture", or "CubeFace Environment".
<code>dds:CubeMapSides</code>	string	For environment maps, which cube faces are present (e.g., "+x -x +y -y" if x & y faces are present, but not z).

Configuration settings for DDS input

When opening an DDS ImageInput with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
<code>oiio:ioproxy</code>	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Additionally, an integer `dds:bc5normal` global attribute is supported to control behaviour of images compressed in BC5/ATI2 compression format. When the attribute value is set to non-zero (default is zero), any input image using BC5/ATI2 compression format is assumed to be a normal map, even if pixel format “normal map” flag is not set.

Custom I/O Overrides

DDS input supports the “custom I/O” feature via the special `"oiio:ioproxy"` attributes (see Sections [Custom I/O proxies \(and writing the file to a memory buffer\)](#) and [Custom I/O proxies \(and reading the file from a memory buffer\)](#)) as well as the `set_ioproxy()` methods.

6.4 DICOM

DICOM (Digital Imaging and Communications in Medicine) is the standard format used for medical images. DICOM files usually have the extension `.dcm`.

OpenImageIO currently only supports reading DICOM files, not writing them.

ImageSpec Attribute	Type	DDS header data or explanation
<code>oiio:BitsPerSample</code>	<code>int</code>	Bits per sample.
<code>dicom:*</code>	<i>any</i>	DICOM header information and metadata is currently all preceded by the <code>dicom:</code> prefix.

6.5 DPX

DPX (Digital Picture Exchange) is an image file format used for motion picture film scanning, output, and digital intermediates. DPX files use the file extension `.dpx`.

Configuration settings for DPX input

When opening a DPX `ImageInput` with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
<code>oiio:RawColor</code>	<code>int</code>	If nonzero, reading images with non-RGB color models (such as YCbCr) will return unaltered pixel values (versus the default OIIO behavior of automatically converting to RGB).
<code>oiio:ioproxy</code>	<code>ptr</code>	Pointer to a <code>Filesystem::IProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.
<code>oiio:subimages</code>	<code>int</code>	The number of “image elements” (subimages) in the file.

Configuration settings for DPX output

When opening a DPX `ImageOutput`, the following special metadata tokens control aspects of the writing itself:

Output configuration Attribute	Type	Meaning
<code>oiio:RawColor</code>	<code>int</code>	If nonzero, writing images with non-RGB color models (such as YCbCr) will keep unaltered pixel values (versus the default OIIO behavior of automatically converting from RGB to the designated color space as the pixels are written).
<code>oiio:dither</code>	<code>int</code>	If nonzero and outputting <code>UINT8</code> values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
<code>oiio:ioproxy</code>	<code>ptr</code>	Pointer to a <code>Filesystem::IProxy</code> that will handle the I/O, for example by writing to memory rather than the file system.

Custom I/O Overrides

DPX input and output both support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

DPX Attributes

ImageSpec Attribute	Type	DPX header data or explanation
ImageDescription	string	Description of image element
Copyright	string	Copyright statement
Software	string	Creator
DocumentName	string	Project name
DateTime	string	Creation date/time
Orientation	int	the orientation of the DPX image data (see <code>metadata:orientation</code>)
compression	string	The compression type
PixelAspectRatio	float	pixel aspect ratio
oiio:BitsPerSample	int	the true bits per sample of the DPX file.
oiio:Endian	string	When writing, force a particular endianness for the output "little" or "big")
smpte:TimeCode	int[2]	SMPTE time code (vecsemantics will be marked as TIMECODE)
smpte:KeyCode	int[7]	SMPTE key code (vecsemantics will be marked as KEYCODE)
dpx:Transfer	string	Transfer characteristic
dpx:Colorimetric	string	Colorimetric specification
dpx:ImageDescriptor	string	ImageDescriptor
dpx:Packing	string	Image packing method
dpx:TimeCode	int	SMPTE time code
dpx:UserBits	int	SMPTE user bits
dpx:SourceDateTime	string	source time and date
dpx:FilmEdgeCode	string	FilmEdgeCode
dpx:Signal	string	Signal ("Undefined", "NTSC", "PAL", etc.)
dpx:UserData	UCHAR[*]	User data (stored in an array whose length is whatever it was in the DPX file)
dpx:EncryptKey	int	Encryption key (-1 is not encrypted)
dpx:DittoKey	int	Ditto (0 = same as previous frame, 1 = new)
dpx:LowData	int	reference low data code value
dpx:LowQuantity	float	reference low quantity
dpx:HighData	int	reference high data code value
dpx:HighQuantity	float	reference high quantity
dpx:XScannedSize	float	X scanned size
dpx:YScannedSize	float	Y scanned size
dpx:FramePosition	int	frame position in sequence
dpx:SequenceLength	int	sequence length (frames)
dpx:HeldCount	int	held count (1 = default)
dpx:FrameRate	float	frame rate of original (frames/s)
dpx:ShutterAngle	float	shutter angle of camera (deg)
dpx:Version	string	version of header format
dpx:Format	string	format (e.g., "Academy")
dpx:FrameId	string	frame identification
dpx:SlateInfo	string	slate information
dpx:SourceImageFileName	string	source image filename
dpx:InputDevice	string	input device name
dpx:InputDeviceSerialNumber	string	input device serial number
dpx:Interlace	int	interlace (0 = noninterlace, 1 = 2:1 interlace)

continues on next page

Table 1 – continued from previous page

ImageSpec Attribute	Type	DPX header data or explanation
dpx:FieldNumber	int	field number
dpx:HorizontalSampleRate	float	horizontal sampling rate (Hz)
dpx:VerticalSampleRate	float	vertical sampling rate (Hz)
dpx:TemporalFrameRate	float	temporal sampling rate (Hz)
dpx:TimeOffset	float	time offset from sync to first pixel (ms)
dpx:BlackLevel	float	black level code value
dpx:BlackGain	float	black gain
dpx:BreakPoint	float	breakpoint
dpx:WhiteLevel	float	reference white level code value
dpx:IntegrationTimes	float	integration time (s)
dpx:EndOfLinePadding	int	Padded bytes at the end of each line
dpx:EndOfImagePadding	int	Padded bytes at the end of each image

6.6 FITS

FITS (Flexible Image Transport System) is an image file format used for scientific applications, particularly professional astronomy. FITS files use the file extension `.fits`. Official FITS specs and other info may be found at: <http://fits.gsfc.nasa.gov/>

OpenImageIO supports multiple images in FITS files, and supports the following pixel data types: UINT8, UINT16, UINT32, FLOAT, DOUBLE.

FITS files can store various kinds of arbitrary data arrays, but OpenImageIO's support of FITS is mostly limited using FITS for image storage. Currently, OpenImageIO only supports 2D FITS data (images), not 3D (volume) data, nor 1-D or higher-dimensional arrays.

ImageSpec Attribute	Type	FITS header data or explanation
Orientation	int	derived from FITS "ORIENTAT" field.
DateTime	string	derived from the FITS "DATE" field.
Comment	string	FITS "COMMENT" (*)
History	string	FITS "HISTORY" (*)
Hierarch	string	FITS "HIERARCH" (*)
oio:subimages	int	The number of subimages in the file.
<i>other</i>		all other FITS keywords will be added to the ImageSpec as arbitrary named metadata.

Note: If the file contains multiple COMMENT, HISTORY, or HIERARCH fields, their text will be appended to form a single attribute (of each) in OpenImageIO's ImageSpec.

6.7 GIF

GIF (Graphics Interchange Format) is an image file format developed by CompuServe in 1987. Nowadays it is widely used to display basic animations despite its technical limitations.

ImageSpec Attribute	Type	GIF header data or explanation
gif:Interlacing	int	Specifies if image is interlaced (0 or 1).
FramesPerSecond	int[2] (ratio- nal)	Frames per second
oiio:Movie	int	If nonzero, indicates that it's a multi-subimage file intended to represent an animation.
oiio:LoopCount	int	Number of times the animation should be played (0-65535, 0 stands for infinity).
gif:LoopCount	int	Deprecated synonym for oiio:LoopCount.
ImageDescription	string	The GIF comment field.

Configuration settings for GIF input

When opening a GIF ImageInput with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for GIF output

When opening a GIF ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to memory rather than the file system.

Custom I/O Overrides

GIF input and output support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections [Custom I/O proxies \(and writing the file to a memory buffer\)](#) and [Custom I/O proxies \(and reading the file from a memory buffer\)](#)) as well as the `set_ioproxy()` methods.

Limitations

- GIF only supports 3-channel (RGB) images and at most 8 bits per channel.
- Each subimage can include its own palette or use global palette. Palettes contain up to 256 colors of which one can be used as background color. It is then emulated with additional Alpha channel by OpenImageIO's reader.

6.8 HDR/RGBE

HDR (High Dynamic Range), also known as RGBE (rgb with extended range), is a simple format developed for the Radiance renderer to store high dynamic range images. HDR/RGBE files commonly use the file extensions `.hdr`. The format is described in this section of the Radiance documentation: <http://radsite.lbl.gov/radiance/refer/filefmts.pdf>

RGBE does not support tiles, multiple subimages, mipmapping, true half or float pixel values, or arbitrary metadata. Only RGB (3 channel) files are supported.

RGBE became important because it was developed at a time when no standard file formats supported high dynamic range, and is still used for many legacy applications and to distribute HDR environment maps. But newer formats with native HDR support, such as OpenEXR, are vastly superior and should be preferred except when legacy file access is required.

Attributes

ImageSpec Attribute	Type	RGBE header data or explanation
Orientation	int	encodes the orientation (see Section <i>Display hints</i>)
oiio:ColorSpace	string	Color space (see Section <i>Color information</i>). We currently assume that any RGBE files encountered are linear with sRGB primaries.
oiio:Gamma	float	the gamma correction specified in the RGBE header (if it's gamma corrected).
heif:Orientation	int	If the configuration option <code>heif:reorient</code> is nonzero and reorientation was performed, this will be set to the original orientation in the file.

Configuration settings for HDR input

When opening an HDR ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.
oiio:reorient	int	The default of 1 means to let libheif auto-reorient the image to undo the camera's orientation (this will set a "heif:Orientation" metadata to the Exif orientation code indicating the original orientation of the image). If this hint is set to 0, the pixels will be left in their orientation as stored in the file, and the "Orientation" metadata will reflect that.

Configuration settings for HDR output

When opening a HDR ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to memory rather than the file system.

Custom I/O Overrides

HDR input and output support the "custom I/O" feature via the special "oiio:ioproxy" attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

6.9 HEIF/HEIC/AVIF

HEIF is a container format for images compressed with various compression standards (HEIC is based on HEVC/H.265, AVIF is based on AV1). HEIC is used commonly for iPhone camera pictures, but it is not Apple-specific and will probably become more popular on other platforms in coming years. HEIF files usually use the file extension .HEIC or .AVIF depending on their main compression type.

HEIC and AVIF compression formats are lossy, but are higher visual quality than JPEG while taking \leq half the file size. Currently, OIIO's HEIF reader supports reading files as RGB or RGBA, uint8 pixel values. Multi-image files are currently supported for reading, but not yet writing. All pixel data is uint8, though we hope to add support for HDR (more than 8 bits) in the future.

The default behavior of the HEIF reader is to reorient the image to the orientation indicated by the camera, and to report the "Orientation" metadata as 1 (indicating that the image should be displayed as returned) and set the "oiio:OriginalOrientation" metadata to what was originally stored in the file. If you want to read the image without automatic reorientation, you can set the configuration option "oiio:reorient" to 0, in which case the pixels will be left in their orientation as stored in the file, and the "Orientation" metadata will reflect that.

Configuration settings for HEIF input

When opening an HEIF ImageInput with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
oiio:UnassociatedAlpha	int	If nonzero, and the file contains unassociated alpha, this will cause the reader to leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).
oiio:reorient	int	If nonzero, asks libheif to reorient any images (and report them as having Orientation 1). If zero, then libheif will not reorient the image and the Orientation metadata will be set to reflect the camera orientation.

Configuration settings for HEIF output

When opening an HEIF ImageOutput, the following special metadata tokens control aspects of the writing itself:

ImageSpec Attribute	Type	HEIF header data or explanation
Compression	string	If supplied, can be "heic" or "avif", but may optionally have a quality value appended, like "heic:90". Quality can be 1-100, with 100 meaning lossless. The default is 75.

6.10 ICO

ICO is an image file format used for small images (usually icons) on Windows. ICO files use the file extension `.ico`.

Attributes

ImageSpec Attribute	Type	ICO header data or explanation
<code>oiio:BitsPerSample</code>	int	the true bits per sample in the ICO file.
<code>ico:PNG</code>	int	if nonzero, will cause the ICO to be written out using PNG format.

Configuration settings for ICO input

When opening an ICO ImageInput with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
<code>oiio:ioproxy</code>	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for ICO output

When opening an ICO ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
<code>oiio:dither</code>	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.

Limitations

- ICO only supports UINT8 and UINT16 formats; all output images will be silently converted to one of these.
- ICO only supports *small* images, up to 256 x 256. Requests to write larger images will fail their `open()` call.

6.11 IFF

IFF files are used by Autodesk Maya and use the file extension `.iff`.

Attributes

ImageSpec Attribute	Type	IFF header data or explanation
<code>Artist</code>	string	The IFF “author”
<code>DateTime</code>	string	Creation date/time
<code>compression</code>	string	The compression type (“none” or “rle” [default])
<code>oiio:BitsPerSample</code>	int	the true bits per sample of the IFF file.

Configuration settings for IFF input

When opening a IFF ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for IFF output

When opening an IFF ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Custom I/O Overrides

RLA input and output support the “custom I/O” feature via the special “oiio:ioproxy” attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

6.12 JPEG

JPEG (Joint Photographic Experts Group), or more properly the JFIF file format containing JPEG-compressed pixel data, is one of the most popular file formats on the Internet, with applications, and from digital cameras, scanners, and other image acquisition devices. JPEG/JFIF files usually have the file extension `.jpg`, `.jpe`, `.jpeg`, `.jif`, `.jfif`, or `.jfi`. The JFIF file format is described by <http://www.w3.org/Graphics/JPEG/jfif3.pdf>.

Although we strive to support JPEG/JFIF because it is so widely used, we acknowledge that it is a poor format for high-end work: it supports only 1- and 3-channel images, has no support for alpha channels, no support for high dynamic range or even 16 bit integer pixel data, by convention stores sRGB data and is ill-suited to linear color spaces, and does not support multiple subimages or MIPmap levels. There are newer formats also blessed by the Joint Photographic Experts Group that attempt to address some of these issues, such as JPEG-2000, but these do not have anywhere near the acceptance of the original JPEG/JFIF format.

Attributes

ImageSpec Attribute	Type	JPEG header data or explanation
ImageDescription	string	the JPEG Comment field
Orientation	int	the image orientation
XResolution, YResolution, ResolutionUnit		The resolution and units from the Exif header
Compression	string	If supplied, must be "jpeg", but may optionally have a quality value appended, like "jpeg:90". Quality can be 1-100, with 100 meaning lossless.
ICCProfile	uint8[]	The ICC color profile. A variety of other ICCProfile:* attributes may also be present, extracted from the main profile.
jpeg:subsampling	string	Describes the chroma subsampling, e.g., "4:2:0" (the default), "4:4:4", "4:2:2", "4:2:1".
Exif:*, IPTC:*, XMP:*, GPS:*		Extensive Exif, IPTC, XMP, and GPS data are supported by the reader/writer, and you should assume that nearly everything described Appendix Metadata conventions is properly translated when using JPEG files.

Configuration settings for JPEG input

When opening a JPEG ImageInput with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a Filesystem::IProxy that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for JPEG output

When opening a JPEG ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a Filesystem::IProxy that will handle the I/O, for example by writing to a memory buffer.
jpeg:iptc	int (1)	If zero, will suppress writing the IPTC metadata block to the JPEG file.
jpeg:progressive	int	If nonzero, will write a progressive JPEG file.

Custom I/O Overrides

JPEG input and output support the “custom I/O” feature via the ImageInput::set_ioproxy() method and the special "oiio:ioproxy" attributes (see Section [Custom I/O proxies \(and reading the file from a memory buffer\)](#)).

Limitations

- JPEG/JFIF only supports 1- (grayscale) and 3-channel (RGB) images. As a special case, OpenImageIO’s JPEG writer will accept n-channel image data, but will only output the first 3 channels (if n >= 3) or the first channel (if n <= 2), silently drop any extra channels from the output.

- Since JPEG/JFIF only supports 8 bits per channel, OpenImageIO's JPEG/JFIF writer will silently convert to UINT8 upon output, regardless of requests to the contrary from the calling program.
- OpenImageIO's JPEG/JFIF reader and writer always operate in scanline mode and do not support tiled image input or output.

6.13 JPEG-2000

JPEG-2000 is a successor to the popular JPEG/JFIF format, that supports better (wavelet) compression and a number of other extensions. It's geared toward photography. JPEG-2000 files use the file extensions `.jp2` or `.j2k`. The official JPEG-2000 format specification and other helpful info may be found at: <http://www.jpeg.org/JPEG2000.htm>

JPEG-2000 is not yet widely used, so OpenImageIO's support of it is preliminary. In particular, we are not yet very good at handling the metadata robustly.

Attributes

ImageSpec Attribute	Type	JPEG-2000 header data or explanation
<code>jpeg2000:streamformat</code>	string	specifies the JPEG-2000 stream format ("none" or "jpc")
<code>oiio:ColorSpace</code>	string	Color space (see Section Color information).
<code>ICCProfile</code>	uint8[]	The ICC color profile. A variety of other <code>ICCProfile:*</code> attributes may also be present, extracted from the main profile.

Configuration settings for JPEG-2000 input

When opening an JPEG-2000 `ImageInput` with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
<code>oiio:UnassociatedAlpha</code>	int	If nonzero, will leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).
<code>oiio:ioproxy</code>	ptr	Pointer to a <code>Filesystem::IProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for JPEG-2000 output

When opening a JPEG-2000 `ImageOutput`, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
<code>oiio:dither</code>	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
<code>oiio:ioproxy</code>	ptr	Pointer to a <code>Filesystem::IProxy</code> that will handle the I/O, for example by writing to a memory buffer.
<code>oiio:UnassociatedAlpha</code>	int	If nonzero, indicates that the data being passed is already in unassociated form (non-premultiplied colors) and should stay that way for output rather than being assumed to be associated and get automatic un-association to store in the file.

Custom I/O Overrides

JPEG-2000 input and output both support the “custom I/O” feature via the special “oiio:ioproxy” attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

6.14 JPEG XL

JPEG XL is a new image format that is designed to be a successor to JPEG and to provide better compression and quality. JPEG XL files use the file extension `.jxl`. The official JPEG XL format specification and other helpful info may be found at: <https://jpeg.org/jpegxl/>

Configuration settings for JPEG XL input

When opening a JPEG XL ImageInput with a *configuration* (see Section *sec-input with-config*), the following special configuration attributes are supported:

Input tribute	Configuration Attribute	Type	Meaning
	oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for JPEG XL output

When opening a JPEG XL ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	JPEG XL header data or explanation
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to a memory buffer.
oiio:UnassociatedAlpha	int	If nonzero, indicates that the data being passed is already in unassociated form (non-premultiplied colors) and should stay that way for output rather than being assumed to be associated and get automatic un-association to store in the file.
compression	string	If supplied, must be "jpegxl", but may optionally have a quality value appended, like "jpegxl:90". Quality can be 0-100, with 100 meaning lossless.
jpegxl:distance	float	Target visual distance in JND units, lower = higher quality. 0.0 = mathematically lossless. 1.0 = visually lossless. Recommended range: 0.5 .. 3.0. Allowed range: 0.0 ... 25.0. Mutually exclusive with *compression jpegxl:*`.
jpegxl:effort	int	Encoder effort setting. Range: 1 .. 10. Default: 7. Higher numbers allow more computation at the expense of time. For lossless, generally it will produce smaller files. For lossy, higher effort should more accurately reach the target quality.
jpegxl:speed	int	Sets the encoding speed tier for the provided options. Minimum is 0 (slowest to encode, best quality/density), and maximum is 4 (fastest to encode, at the cost of some quality/density). Default is 0. (Note: in libjxl it named <code>JXL_ENC_FRAME_SETTING_DECODING_SPEED</code> . But it is about encoding speed and compression quality, not decoding speed.)
jpegxl:photon_noise_iso	float	(<code>ISO_FILM_SPEED</code>) Adds noise to the image emulating photographic film or sensor noise. Higher number = grainier image, e.g. 100 gives a low amount of noise, 3200 gives a lot of noise. Default is 0. Encoded as metadata in the image.
jpegxl:use_boxes	int (bool)	If nonzero, will enable metadata (Exif, XMP, jumb, iptc) writing to the output file. Default is 1.
jpegxl:compress_boxes	int (bool)	If nonzero, will enable metadata compression. Default is 1.
jpegxl:exif_box	int (bool)	If nonzero, will enable Exif metadata writing to the output file. Default is 1.
jpegxl:xmp_box	int (bool)	If nonzero, will enable XMP metadata writing to the output file. Default is 1.
jpegxl:jumb_box	int (bool)	If nonzero, will enable JUMBF metadata writing to the output file. Default is 0. (does not supported at this moment in OIIO)
jpegxl:iptc_box	int (bool)	If nonzero, will enable IPTC metadata writing to the output file. Default is 0. (Does not work as expected at this moment. Box is written but content unreadable in exif readers.)

6.15 Movie formats (using ffmpeg)

The **ffmpeg**-based reader is capable of reading the individual frames from a variety of movie file formats, including:

Format	Extensions
AVI	.avi
QuickTime	.qt, .mov
MPEG-4	.mp4, .m4a, .m4v
3GPP files	.3gp, .3g2
Motion JPEG-2000	.mj2
Apple M4V	.m4v
MPEG-1/MPEG-2	.mpg

The format list include may other file types as well. We rely on the **ffmpeg** library to read these files, so the actual list of supported formats may vary depending on the version of **ffmpeg** that was linked into OpenImageIO.

Currently, these files may only be read. Write support may be added in a future release. Also, currently, these files simply look to OIIO like simple multi-image files and not much support is given to the fact that they are technically *movies* (for example, there is no support for reading audio information).

Some special attributes are used for movie files:

ImageSpec Attribute	Type	Header data or explanation
oiio:Movie	int	Nonzero value for movie files
oiio:subimages	int	The number of frames (subimages) in the movie.
FramesPerSecond	int[2] (ratio- nal)	Frames per second
ffmpeg:TimeCode	string	Start time timecode

6.16 Null format

The **nullptr** reader/writer is a mock-up that does not perform any actual I/O. The reader just returns constant-colored pixels, and the writer just returns directly without saving any data. This has several uses:

- Benchmarking, if you want to have OIIO's input or output truly take as close to no time whatsoever.
- “Dry run” of applications where you don't want it to produce any real output (akin to a Unix command that you redirect output to `/dev/null`).
- Make “fake” input that looks like a file, but the file doesn't exist (if you are happy with constant-colored pixels).

The filename allows a REST-ful syntax, where you can append modifiers that specify things like resolution (of the non-existent file), etc. For example:

```
foo.null?RES=640x480&CHANNELS=3
```

would specify a null file with resolution 640x480 and 3 channels. Token/value pairs accepted are:

RES=1024x1024	Set resolution (3D example: 256x256x100)
CHANNELS=4	Set number of channels
TILES=64x64	Makes it look like a tiled image with tile size
TYPE=uint8	Set the pixel data type
PIXEL=r,g,b,...	Set pixel values (comma separates channel values)
TEX=1	Make it look like a full MIP-mapped texture
attrib=value	Anything else will set metadata

6.17 OpenEXR

OpenEXR is an image file format developed by Industrial Light & Magic, and subsequently open-sourced. OpenEXR's strengths include support of high dynamic range imagery (`half` and `float` pixels), tiled images, explicit support of MIPmaps and cubic environment maps, arbitrary metadata, and arbitrary numbers of color channels. OpenEXR files use the file extension `.exr`. The official OpenEXR site is <http://www.openexr.com/>.

Attributes

ImageSpec Attribute	Type	OpenEXR header data or explanation
width, height, x, y	int	dataWindow
full_width, full_height, full_x, full_y	int	displayWindow
worldtocamera	matrix	worldToCamera
worldtoscreen	matrix	worldToScreen
worldtoNDC	matrix	worldToNDC
ImageDescription	string	comments
Copyright	string	owner
DateTime	string	capDate
PixelAspectRatio	float	pixelAspectRatio
ExposureTime	float	expTime
FNumber	float	aperture
compression	string	one of: "none", "rle", "zip", "zips", "piz", "pxr24", "b44", "b44a", "dwa", or "dwab". If the writer receives a request for a compression type it does not recognize or is not supported by the version of OpenEXR on the system, it will use "zip" by default. For "dwa" and "dwab", the dwaCompressionLevel may be optionally appended to the compression name after a colon, like this: "dwa:200". (The default DWA compression value is 45.) For "zip" and "zips" compression, a level from 1 to 9 may be appended (the default is "zip:4"), but note that this is only honored when building against OpenEXR 3.1.3 or later.
textureformat	string	"Plain Texture" for MIP-mapped OpenEXR files, "CubeFace Environment" or "Latlong Environment" for OpenEXR environment maps. Non-environment non-MIP-mapped OpenEXR files will not set this attribute.
wrapmodes	string	wrapmodes
FramesPerSecond	int[2]	Frames per second playback rate (vec semantics will be marked as RATIONAL)
captureRate	int[2]	Frames per second capture rate (vec semantics will be marked as RATIONAL)
oiio:subimages	int	The number of "parts" (subimages) in the file.
smpte:TimeCode	int[2]	SMPTE time code (vec semantics will be marked as TIMECODE)
smpte:KeyCode	int[7]	SMPTE key code (vec semantics will be marked as KEYCODE)
openexr:lineOrder	string	OpenEXR lineOrder attribute: "increasingY", "randomY", or "decreasingY".
openexr:roundingmode	int	the MIPmap rounding mode of the file.
openexr:dwaCompressionLevel	float	compression level for dwa or dwab compression (default: 45.0).
openexr::luminancechroma	int	If nonzero, indicates whether the image is a luminance-chroma image. Upon reading, the subsampled Y/BY/R(Y/A) channels of luminance-chroma images are automatically converted to RGB(A) channels.
other		All other attributes will be added to the ImageSpec by their name and apparent type.

Configuration settings for OpenEXR input

When opening an OpenEXR ImageInput with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.
oiio:missingcolor	float <i>or</i> string	Either an array of float values or a string holding a comma-separated list of values, if present this is a request to use this color for pixels of any missing tiles or scanlines, rather than considering a tile/scanline read failure to be an error. This can be helpful when intentionally reading partially-written or incomplete files (such as an in-progress render).

Configuration settings for OpenEXR output

When opening an OpenEXR ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:RawColor	int	If nonzero, writing images with non-RGB color models (such as YCbCr) will keep unaltered pixel values (versus the default OIIO behavior of automatically converting from RGB to the designated color space as the pixels are written).
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to a memory buffer.

Custom I/O Overrides

OpenEXR input and output both support the “custom I/O” feature via the special “oiio:ioproxy” attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

A note on channel names

The underlying OpenEXR library (`libIlmImf`) always saves channels into lexicographic order, so the channel order on disk (and thus when read!) will NOT match the order when the image was created.

But in order to adhere to OIIO’s convention that RGBAZ will always be the first channels (if they exist), OIIO’s OpenEXR reader will automatically reorder just those channels to appear at the front and in that order. All other channel names will remain in their relative order as presented to OIIO by `libIlmImf`.

Limitations

- The OpenEXR format only supports HALF, FLOAT, and UINT32 pixel data. OpenImageIO’s OpenEXR writer will silently convert data in formats (including the common UINT8 and UINT16 cases) to HALF data for output.
- Subsampled channels are not supported with the exception of reading luminance-chroma images with vertical and horizontal sampling rates of 2. This limited support does not work when OpenEXR’s C Core API is used, only when OpenEXR’s C++ API is used. Furthermore, it does not work in combination with tiles, multiple subimages, mipmapping, or deep pixels.

6.18 OpenVDB

OpenVDB is an open-source volume data file format. OpenVDB files commonly use the extension `.vdb`. The official OpenVDB site is: <http://www.openvdb.org/> Currently, OpenImageIO only reads OpenVDB files, and does not write them.

Volumes are comprised of multiple *layers* (which appear to OpenImageIO as subimages). Each layer/subimage may have a different name, resolution, and coordinate mapping. Layers may be scalar (1 channel) or vector (3 channel) fields, and the voxel data are always `float`. OpenVDB files always report as tiled, using the leaf dimension size.

Attributes

ImageSpec Attribute	Type	OpenVDB header data or explanation
ImageDescription	string	Description of image element
oio:subimagename	string	unique layer name
oio:subimages	int	The number of “layers” (subimages) in the file.
openvdb:indextoworld	matrix of doubles	conversion of voxel index to world space coordinates.
openvdb:worldtoindex	matrix of doubles	conversion of world space coordinates to voxel index.
worldtocamera	matrix	World-to-local coordinate mapping.

6.19 PNG

PNG (Portable Network Graphics) is an image file format developed by the open source community as an alternative to the GIF, after Unisys started enforcing patents allegedly covering techniques necessary to use GIF. PNG files use the file extension `.png`.

Attributes

ImageSpec Attribute	Type	PNG header data or explanation
ImageDescription	string	Description
Artist	string	Author
DocumentName	string	Title
DateTime	string	the timestamp in the PNG header
PixelAspectRatio	float	pixel aspect ratio
XResolution, YResolution, ResolutionUnit		resolution and units from the PNG header.
oio:ColorSpace	string	Color space (see Section Color information).
oio:Gamma	float	the gamma correction value (if specified).
ICCProfile	uint8[]	The ICC color profile. A variety of other <code>ICCProfile:*</code> attributes may also be present, extracted from the main profile.

Configuration settings for PNG input

When opening an PNG ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
oiio:UnassociatedAlpha	int	If nonzero, will leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for PNG output

When opening an PNG ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to a memory buffer.
png:compressionLevel	int	Compression level for zip/deflate compression, on a scale from 0 (fastest, minimal compression) to 9 (slowest, maximal compression). The default is 6. PNG compression is always lossless.
png:filter	int	Controls the “row filters” that prepare the image for optimal compression. The default is 0 (PNG_NO_FILTERS), but other values (which may be “or-ed” or summed to combine their effects) are 8 (PNG_FILTER_NONE), 16 (PNG_FILTER_SUB), 32 (PNG_FILTER_UP), 64 (PNG_FILTER_AVG), or 128 (PNG_FILTER_PAETH). Important: We have noticed that 8 (PNG_FILTER_NONE) is much faster than the default of NO_FILTERS (sometimes 3x or more faster), but it also makes the resulting files quite a bit larger (sometimes 2x larger). If you need to optimize PNG write speed and are willing to have larger PNG files on disk, you may want to use that value for this attribute.

Custom I/O Overrides

PNG input and output both support the “custom I/O” feature via the special “oiio:ioproxy” attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

Limitations

- PNG stupidly specifies that any alpha channel is “unassociated” (i.e., that the color channels are not “premultiplied” by alpha). This is a disaster, since it results in bad loss of precision for alpha image compositing, and even makes it impossible to properly represent certain additive glows and other desirable pixel values. OpenImageIO automatically associates alpha (i.e., multiplies colors by alpha) upon input and deassociates alpha (divides colors by alpha) upon output in order to properly conform to the OIIO convention (and common sense) that all pixel values passed through the OIIO APIs should use associated alpha.
- PNG only supports UINT8 and UINT16 output; other requested formats will be automatically converted to one of these.

6.20 PNM / Netpbm

The Netpbm project, a.k.a. PNM (portable “any” map) defines PBM, PGM, PPM and later added PFM (portable float map) as a set of simple image formats (portable bitmap, portable graymap, portable pixmap) files. Without loss of generality, we will refer to these all collectively as “PNM.” These files have extensions `.pbm`, `.pgm`, `.ppm`, `.pfm` and customarily correspond to bi-level bitmaps, 1-channel grayscale, and 3-channel RGB files, respectively, or `.pnm` for those who reject the nonsense about naming the files depending on the number of channels and bitdepth.

PNM files are widely used in the Unix world as simple ASCII or binary image files that are easy to read and write. They are not compressed, and are not particularly efficient for large images. They are not widely used in the professional graphics world, but because of their historical significance and extreme simplicity, OpenImageIO supports them. PNM files do not support anything other than 1 or 3 channels, no tiles, no multi-image, no MIPmapping.

The `pbm`, `pgm`, and `ppm` varieties are stored with scanlines ordered in the file as top-to-bottom (the same as the usual OIIO convention), but the float-based `pfm` files are conventionally ordered in the file as bottom-to-top. Therefore, by default, reading and writing of the `pfm` variety will automatically flip the image so that an application calling the OpenImageIO API can, as usual, assume that scanline 0 is the visual “top” (even though it is actually the last scanline stored in the file).

Both the reader and writer accept configuration hints “`pnm:pfmflip`” (default: 1), which if set to 0 will disable this flipping and ensure that scanline 0 is written as the first in the file (therefore representing what PFM assumes is the visual “bottom” of the image). This hint only affects PFM files and has no effect on the `pbm`, `pgm`, or `ppm` varieties.

Attributes

ImageSpec Attribute	Type	PNM header data or explanation
<code>oiio:BitsPerSample</code>	int	The true bits per sample of the file (1 for true PBM files, even though OIIO will report the <code>format</code> as <code>UINT8</code>).
<code>pnm:binary</code>	int	nonzero if the file itself used the PNM binary format, 0 if it used ASCII. The PNM writer honors this attribute in the ImageSpec to determine whether to write an ASCII or binary file.

Configuration settings for PNM input

When opening a PNM ImageInput with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
<code>oiio:ioproxy</code>	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.
<code>pnm:bigendian</code>	int	If nonzero, the PNM file is big-endian (the default is little-endian).
<code>pnm:pfmflip</code>	int	If this configuration hint is present and is zero, the automatic vertical flipping of PFM image will be disabled (i.e., scanline 0 will really be the first one stored in the file). If nonzero (the default), float PFM files will store scanline 0 as the last scanline in the file (i.e. the visual “top” of the image).

Configuration settings for PNM output

When opening a PNM ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IProxy</code> that will handle the I/O, for example by writing to a memory buffer.
pnm:bigendian	int	If nonzero, the PNM file is big-endian (the default is little-endian).
pnm:binary	int	nonzero if the file itself used the PNM binary format, 0 if it used ASCII. The PNM writer honors this attribute in the <code>ImageSpec</code> to determine whether to write an ASCII or binary file. Float PFM files are always written in binary format.
pnm:pfmflip	int	If this configuration hint is present and is zero, for PFM files, scanline 0 will really be stored first in the file, thus disabling the usual automatically flipping that accounts for PFM files conventionally being stored in bottom-to-top order. If nonzero (the default), float PFM files will store scanline 0 as the last scanline in the file (i.e. the visual “top” of the image).

Custom I/O Overrides

PNM input and output both support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

6.21 PSD

PSD is the file format used for storing Adobe PhotoShop images. OpenImageIO provides limited read abilities for PSD, but not currently the ability to write PSD files.

Attributes

ImageSpec Attribute	Type	JPEG header data or explanation
ICCProfile	uint8[]	The ICC color profile. A variety of other <code>ICCProfile:*</code> attributes may also be present, extracted from the main profile.

Configuration settings for PSD input

When opening an `ImageInput` with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
oiio:RawColor	int	If nonzero, reading images with non-RGB color models (such as YCbCr or CMYK) will return unaltered pixel values (versus the default OIIO behavior of automatically converting to RGB).
oiio:UnassociatedAlpha	int	If nonzero, will leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Currently, the PSD format reader supports color modes RGB, CMYK, multichannel, grayscale, indexed, and bitmap. It does NOT currently support Lab or duotone modes.

Custom I/O Overrides

PSD input supports the “custom I/O” feature via the special “oiio:ioproxy” attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

6.22 Ptex

Ptex is a special per-face texture format developed by Walt Disney Feature Animation. The format and software to read/write it are open source, and available from <http://ptex.us/>. Ptex files commonly use the file extension `.ptex`.

OpenImageIO’s support of Ptex is still incomplete. We can read pixels from Ptex files, but the `TextureSystem` doesn’t properly filter across face boundaries when using it as a texture. OpenImageIO currently does not write Ptex files at all.

Attributes

ImageSpec Attribute	Type	Ptex header data or explanation
ptex:meshType	string	the mesh type, either “triangle” or “quad”.
ptex:hasEdits	int	nonzero if the Ptex file has edits.
wrapmode	string	the wrap mode as specified by the Ptex file.
<i>other</i>		Any other arbitrary metadata in the Ptex file will be stored directly as attributes in the ImageSpec.

6.23 RAW digital camera files

A variety of digital camera “raw” formats are supported via this plugin that is based on the LibRaw library (<http://www.libraw.org/>).

Configuration settings for RAW input

When opening an ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
raw:auto_bright	int	If nonzero, will use libraw's exposure correction. (Default: 0)
raw:use_camera_wb	int	If 1, use libraw's camera white balance adjustment. Takes precedence over raw:use_auto_wb, raw:greybox, raw:user_mul. (Default: 1)
raw:use_auto_wb	int	If 1, white balance automatically by averaging over the entire image. Only applies if raw:use_camera_wb is not equal to 0. Takes precedence over raw:greybox, raw:user_mul. (Default: 0)
raw:greybox	int[4]	White balance by averaging over the given box. The four values are the X and Y coordinate of the top-left corner, the width and the height. Only applies if the size is non-zero, and raw:use_camera_wb is not equal to 0, raw:use_auto_wb is not equal to 0. Takes precedence over raw:user_mul. (Default: 0, 0, 0, 0; meaning no correction.)
raw:cropbox	int[4]	If present, sets the box to crop the image to. The four values are the X and Y coordinate of the top-left corner, the width and the height. If not present, the image is cropped to match the in-camera JPEG, assuming the necessary information is present in the metadata. The cropping is done by setting the display window, so the whole image pixels are still available. The default cropping can be disabled by setting the cropbox to zero size.
raw:use_camera_matrix	int	Whether to use the embedded color profile, if it's present: 0 = never, 1 (default) = only for DNG files, 3 = always.
raw:adjust_maximum_thr	float	If nonzero, auto-adjusting maximum value. (Default: 0.0)
raw:user_black	int	If not negative, sets the camera minimum value that will be normalized to appear 0. (Default: -1)
raw:user_sat	int	If nonzero, sets the camera maximum value that will be normalized to appear saturated. (Default: 0)
raw:aber	float[2]	Red and blue scale factors for chromatic aberration correction when decoding the raw image. The default (1,1) means to perform no correction. This is an overall spatial scale, sensible values will be very close to 1.0.
raw:half_size	int	If nonzero, outputs the image in half size. (Default: 0)
raw:user_mul	float[4]	Sets user white balance coefficients. Only applies if raw:use_camera_wb is not equal to 0, raw:use_auto_wb is not equal to 0, and the raw:greybox box is zero size.
raw:ColorSpace	string	Which color primaries to use for the returned pixel values: raw, sRGB, sRGB-linear (sRGB primaries, but a linear transfer function), Adobe, Wide, ProPhoto, ProPhoto-linear, XYZ, ACES (only supported by LibRaw >= 0.18), DCI-P3 (LibRaw >= 0.21), Rec2020 (LibRaw >= 0.2). (Default: sRGB)
raw:Exposure	float	Amount of exposure before de-mosaicing, from 0.25 (2 stop darken) to 8.0 (3 stop brighten). (Default: 1.0, meaning no correction.)
raw:Demosaic	string	Force a demosaicing algorithm: linear, VNG, PPG, AHD (default), DCB, AHD-Mod, AFD, VCD, Mixed, LMMSE, AMaZE, DHT, AAHD, none.
raw:HighlightMode	int	Set libraw highlight mode processing: 0 = clip, 1 = unclip, 2 = blend, 3+ = rebuild. (Default: 0.)
raw:balance_clamped	int	If nonzero, balance any clamped highlight values in the image. Resolves issues where highlights take on an undesired hue shift due to incongruous channel sensor saturation. Enabling this option will change the output datatype to HALF. (Default: 0)
raw:apply_scene_linear_scale	int	If nonzero, applies an additional multiplication to the pixel values returned by libraw. See raw:camera_to_scene_linear_scale for more details. Enabling this option will change the output datatype to HALF. (Default: 0)
raw:camera_to_scene_linear_scale	float	Whilst the libraw pixel values are linear, they are normalized based on the whitepoint / sensor / ISO and shooting conditions. An additional multiplication is needed to bring exposure levels up so that a correctly photographed 18% grey card has pixel values at 0.18. Setting

6.24 RLA

RLA (Run-Length encoded, version A) is an early CGI renderer output format, originating from Wavefront Advanced Visualizer and used primarily by software developed at Wavefront. RLA files commonly use the file extension `.rla`.

Attributes

ImageSpec Attribute	Type	RLA header data or explanation
<code>width, height, x, y</code>	int	RLA “active/viewable” window.
<code>full_width, full_height, full_x, full_y</code>	int	RLA “full” window.
<code>rla:FrameNumber</code>	int	frame sequence number.
<code>rla:Revision</code>	int	file format revision number, currently <code>0xFFFE</code> .
<code>rla:JobNumber</code>	int	job number ID of the file.
<code>rla:FieldRendered</code>	int	whether the image is a field-rendered (interlaced) one 0 for false, non-zero for true.
<code>rla:FileName</code>	string	name under which the file was originally saved.
<code>ImageDescription</code>	string	RLA “Description” of the image.
<code>Software</code>	string	name of software used to save the image.
<code>HostComputer</code>	string	name of machine used to save the image.
<code>Artist</code>	string	RLA “UserName”: logon name of user who saved the image.
<code>rla:Aspect</code>	string	aspect format description string.
<code>rla:ColorChannel</code>	string	textual description of color channel data format (usually <code>rgb</code>).
<code>rla:Time</code>	string	description (format not standardized) of amount of time spent on creating the image.
<code>rla:Filter</code>	string	name of post-processing filter applied to the image.
<code>rla:AuxData</code>	string	textual description of auxiliary channel data format.
<code>rla:AspectRatio</code>	float	image aspect ratio.
<code>rla:RedChroma</code>	vec2 or vec3 of floats	red point XY (vec2) or XYZ (vec3) coordinates.
<code>rla:GreenChroma</code>	vec2 or vec3 of floats	green point XY (vec2) or XYZ (vec3) coordinates.
<code>rla:BlueChroma</code>	vec2 or vec3 of floats	blue point XY (vec2) or XYZ (vec3) coordinates.
<code>rla:WhitePoint</code>	vec2 or vec3 of floats	white point XY (vec2) or XYZ (vec3) coordinates.
<code>oiio:ColorSpace</code>	string	Color space (see Section Color information).
<code>oiio:Gamma</code>	float	the gamma correction value (if specified).

Configuration settings for RLA input

When opening a RLA ImageInput with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for RLA output

When opening a RLA ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Custom I/O Overrides

RLA input and output support the “custom I/O” feature via the special “oiio:ioproxy” attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

Limitations

- OpenImageIO will only write a single image to each file, multiple subimages are not supported by the writer (but are supported by the reader).

6.25 SGI

The SGI image format was a simple raster format used long ago on SGI machines. SGI files use the file extensions `sgi`, `rgb`, `rgba`, `bw`, `int`, and `inta`.

The SGI format is sometimes used for legacy apps, but has little merit otherwise: no support for tiles, no MIPmaps, no multi-subimage, only 8- and 16-bit integer pixels (no floating point), only 1-4 channels.

Attributes

ImageSpec Attribute	Type	SGI header data or explanation
compression	string	The compression of the SGI file (<code>rle</code> , if RLE compression is used).
ImageDescription	string	Image name.

Configuration settings for SGI input

When opening a SGI ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for SGI output

When opening an SGI ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Custom I/O Overrides

SGI input and output support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

6.26 Softimage PIC

Softimage PIC is an image file format used by the SoftImage 3D application, and some other programs that needed to be compatible with it. Softimage files use the file extension `.pic`.

The Softimage PIC format is sometimes used for legacy apps, but has little merit otherwise, so currently OpenImageIO only reads Softimage files and is unable to write them.

Attributes

ImageSpec Attribute	Type	PIC header data or explanation
compression	string	The compression of the SGI file (rle, if RLE compression is used).
ImageDescription	string	Comment
oiio:BitsPerSample	int	the true bits per sample of the PIC file.

6.27 Targa

Targa (a.k.a. Truevision TGA) is an image file format with little merit except that it is very simple and is used by many legacy applications. Targa files use the file extension `.tga`, or, much more rarely, `.tpic`. The official Targa format specification may be found at: <http://www.dca.fee.unicamp.br/~martino/disciplinas/ea978/tgaffs.pdf>

Attributes

ImageSpec Attribute	Type	TGA header data or explanation
ImageDescription	string	Comment
Artist	string	author
DocumentName	string	job name/ID
Software	string	software name
DateTime	string	TGA time stamp
targa:JobTime	string	TGA “job time.”
compression	string	values of none and rle are supported. The writer will use RLE compression if any unknown compression methods are requested.
targa:alpha_type	int	Meaning of any alpha channel (0 = none; 1 = undefined, ignore; 2 = undefined, preserve; 3 = useful unassociated alpha; 4 = useful associated alpha / premultiplied color).
targa:ImageID	string	Image ID
targa:JobTime	string	Job time
targa:version	int	TGA file format version (1 or 2)
PixelAspectRatio	float	pixel aspect ratio
oiio:BitsPerSample	int	the true bits per sample of the PIC file.
oiio:ColorSpace	string	Color space (see Section Color information).
oiio:Gamma	float	the gamma correction value (if specified).

If the TGA file contains a thumbnail, its dimensions will be stored in the attributes "thumbnail_width", "thumbnail_height", and "thumbnail_nchannels", and the thumbnail pixels themselves will be retrievable via `ImageInput::get_thumbnail()` or `ImageBuf::thumbnail()` or `ImageCache::get_thumbnail()`.

Configuration settings for Targa input

When opening a Targa `ImageInput` with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.
oiio:UnassociatedAlpha	int	If nonzero, and the file contains unassociated alpha, this will cause the reader to leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).

Configuration settings for Targa output

When opening a Targa `ImageOutput`, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to a memory buffer.

Custom I/O Overrides

Targa input and output support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections [Custom I/O proxies \(and writing the file to a memory buffer\)](#) and [Custom I/O proxies \(and reading the file from a memory buffer\)](#)) as well as the `set_ioproxy()` methods.

Limitations

- The Targa reader reserves enough memory for the entire image. Therefore it is not a good choice for high-performance image use such as would be used for ImageCache or TextureSystem.
- Targa files only support 8- and 16-bit unsigned integers (no signed, floating point, or HDR capabilities); the OpenImageIO TGA writer will silently convert all output images to UINT8 (except if UINT16 is explicitly requested).
- Targa only supports grayscale, RGB, and RGBA; the OpenImageIO TGA writer will fail its call to `open()` if it is asked create a file with more than 4 color channels.

6.28 Term (Terminal)

This *experimental* output-only “format” is actually a procedural output that writes a low-res representation of the image to the console output. It requires a terminal application that supports Unicode and 24 bit color extensions.

The `term` ImageOutput supports the following special metadata tokens to control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
<code>term:method</code>	string	May be one of <code>iterm2</code> , <code>24bit</code> (default), <code>24bit-space</code> , <code>256color</code> , or <code>dither</code> .
<code>term:fit</code>	int	If 1 (the default), the image will be resized to fit on the console window.

The `iterm2` mode is the best quality and is the default mode when actually running on a Mac and launching using iTerm2 as the terminal. This mode uses iTerm2’s nonstandard extension to directly output an pixel array to be visible in the terminal.

The default in other circumstances is the `24bit` mode, which displays two approximately square pixels vertically in each character cell, by outputting the Unicode “upper half block” glyph (`u2508`) with the foreground color set to the top pixel’s color and the background color set to the bottom pixel’s color.

If this doesn’t look right, or your terminal doesn’t support Unicode, the `24bit-space` is an alternate mode that displays one elongated pixel in each character cell, writing a space character with the correct color.

There’s also a `256color` method that just uses the 6x6x6 color space in the 256 color palette – which looks horrible – and an experimental `dither` which does a half-assed Floyd-Steinberg dithering, horizontally only, and frankly is not an improvement unless you squint really hard. These may change or be eliminated in the future.

In all cases, the image will automatically be resized to fit in the terminal and keep approximately the correct aspect ratio, as well as converted to sRGB so it looks kinda ok.

6.29 TIFF

TIFF (Tagged Image File Format) is a flexible file format created by Aldus, now controlled by Adobe. TIFF supports nearly everything anybody could want in an image format (and has exactly the complexity you would expect from such a requirement). TIFF files commonly use the file extensions `.tif` or `.tiff`. Additionally, OpenImageIO associates the following extensions with TIFF files by default: `.tx`, `.env`, `.sm`, `.vsm`.

The official TIFF format specification may be found here: <http://partners.adobe.com/public/developer/tiff/index.html>
The most popular library for reading TIFF directly is `libtiff`, available here: <http://www.remotesensing.org/libtiff/>
OpenImageIO uses `libtiff` for its TIFF reading/writing.

We like TIFF a lot, especially since its complexity can be nicely hidden behind OIIO's simple APIs. It supports a wide variety of data formats (though unfortunately not `half`), an arbitrary number of channels, tiles and multiple subimages (which makes it our preferred texture format), and a rich set of metadata.

OpenImageIO supports the vast majority of TIFF features, including: tiled images (`tiled`) as well as scanline images; multiple subimages per file (`multiimage`); MIPmapping (using multi-subimage; that means you can't use `multiimage` and `MIPmaps` simultaneously); data formats 8- 16, and 32 bit integer (both signed and unsigned), and 32- and 64-bit floating point; palette images (will convert to RGB); "miniswhite" photometric mode (will convert to "minisblack").

The TIFF plugin attempts to support all the standard Exif, IPTC, and XMP metadata if present.

Configuration settings for TIFF input

When opening an `ImageInput` with a *configuration* (see Section [Opening for input with configuration settings/hints](#)), the following special configuration options are supported:

Input Configuration Attribute	Type	Meaning
<code>oiio:UnassociatedAlpha</code>	<code>int</code>	If nonzero, and the file contains unassociated alpha, this will cause the reader to leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).
<code>oiio:RawColor</code>	<code>int</code>	If nonzero, reading images with non-RGB color models (such as YCbCr) will return unaltered pixel values (versus the default OIIO behavior of automatically converting to RGB).
<code>oiio:ioproxy</code>	<code>ptr</code>	Pointer to a <code>Filesystem::IProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for TIFF output

When opening an `ImageOutput`, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:BitsPerSample	int	Requests a rescaling to a specific bits per sample (such as writing 12-bit TIFFs).
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to memory rather than the file system.
oiio:UnassociatedAlpha	int	If nonzero, any alpha channel is understood to be unassociated, and the EXTRASAMPLES tag in the TIFF file will be set to reflect this).
tiff:write_exif	int	If zero, will not write any Exif data to the TIFF file. (The default is 1.)
tiff:half	int	If nonzero, allow writing TIFF files with half (16 bit float) pixels. The default of 0 will automatically translate to float pixels, since most non-OIIO applications will not properly read half TIFF files despite their being legal.
tiff:ColorSpace	string	Requests that the RGB image be converted and saved in the TIFF file in a non-RGB color space. Choices are RGB, CMYK. (Note that YCbCr, CIELAB, ICCLAB, ITULAB are not yet supported for conversion. However, if the oiio:ColorSpace is one of those, meaning that the image data is presumed to already be in that space, the TIFF PhotometricInterpretation tag will be set to convey this information.)
tiff:zipquality	int	A time-vs-space knob for zip compression, ranging from 1-9 (default is 6). Higher means compress to less space, but taking longer to do so. It is strictly a time vs space tradeoff, the visual image quality is identical (lossless) no matter what the setting.
tiff:RowsPerStrip	int	Overrides TIFF scanline rows per strip with a specific request (if not supplied, OIIO will choose a reasonable default).
tiff:bigtiff	int	If nonzero, forces use of “bigtiff,” a nonstandard extension that allows files to be more than 4 GB (default: 0).
tiff:write_extrasamples	int	If zero, do NOT write the “EXTRASAMPLES” tag to the TIFF header. (The default is 1, which means write the tag.)
tiff:write_iptc	int	If nonzero, write an IPTC data block to the TIFF file. (The default is 0, which means not to write an IPTC block.)

TIFF compression modes

The full list of possible TIFF compression mode values are as follows.

```
none * lzw * zip * ccitt_t4 ccitt_t6 ccittfax3 ccittfax4 ccittrle2 ccittrle * dcs isojobig
IT8BL IT8CTPAD IT8LW IT8MP jp2000 jpeg * lzma next ojpeg packbits * pxiarfilm pxiarlog
sgilog24 sgilog T43 T85 thunderscan
```

* indicates that OpenImageIO can write that format, and is not part of the format name. The compression types without the asterisk are supported for reading but not for writing.

Custom I/O Overrides

TIFF input and output support the “custom I/O” feature via the `ImageInput::set_ioproxy()` method and the special “oiio:ioproxy” attributes (see Section *Custom I/O proxies (and reading the file from a memory buffer)*).

Limitations

OpenImageIO’s TIFF reader and writer have some limitations you should be aware of:

- No separate per-channel data formats (not supported by `libtiff`).

- Only multiples of 8 bits per pixel may be passed through OpenImageIO's APIs, e.g., 1-, 2-, and 4-bits per pixel will be passed by OIIO as 8 bit images; 12 bits per pixel will be passed as 16, etc. But the `oiio:BitsPerSample` attribute in the `ImageSpec` will correctly report the original bit depth of the file. Similarly for output, you must pass 8 or 16 bit output, but `oiio:BitsPerSample` gives a hint about how you want it to be when written to the file, and it will try to accommodate the request (for signed integers, TIFF output can accommodate 2, 4, 8, 10, 12, and 16 bits).
- JPEG compression is limited to 8-bit per channel, 3-channel files.

TIFF Attributes

ImageSpec Attribute	Type	TIFF header data or explanation
<code>ImageSpec::x</code>	int	XPosition
<code>ImageSpec::y</code>	int	YPosition
<code>ImageSpec::full_width</code>	int	PIXAR_IMAGEFULLWIDTH
<code>ImageSpec::full_length</code>	int	PIXAR_IMAGEFULLLENGTH
<code>ImageDescription</code>	string	ImageDescription
<code>DateTime</code>	string	DateTime
<code>Software</code>	string	Software
<code>Artist</code>	string	Artist
<code>Copyright</code>	string	Copyright
<code>Make</code>	string	Make
<code>Model</code>	string	Model
<code>DocumentName</code>	string	DocumentName
<code>HostComputer</code>	string	HostComputer
<code>XResolution, YResolution</code>	float	XResolution, YResolution
<code>ResolutionUnit</code>	string	ResolutionUnit (in or cm).
<code>Orientation</code>	int	Orientation
<code>ICCProfile</code>	uint8[]	The ICC color profile. A variety of other <code>ICCProfile:*</code> attributes may also be present, extracted from the main profile.
<code>textureformat</code>	string	PIXAR_TEXTUREFORMAT
<code>wrapmodes</code>	string	PIXAR_WRAPMODES
<code>fovcot</code>	float	PIXAR_FOVCOT
<code>worldtocamera</code>	matrix	PIXAR_MATRIX_WORLDTOCAMERA
<code>worldtoscreen</code>	matrix	PIXAR_MATRIX_WORLDTOSCREEN
<code>compression</code>	string	based on TIFF Compression (one of none, lzw, zip, or others listed above).
<code>tiff:compression</code>	int	the original integer code from the TIFF Compression tag.
<code>tiff:planarconfig</code>	string	PlanarConfiguration (separate or contig). The OpenImageIO TIFF writer will honor such a request in the <code>ImageSpec</code> .
<code>tiff:PhotometricInterpretation</code>	int	Photometric
<code>tiff:PageName</code>	string	PageName
<code>tiff:PageNumber</code>	int	PageNumber
<code>tiff:RowsPerStrip</code>	int	RowsPerStrip
<code>tiff:subfiletype</code>	int	SubfileType
<code>Exif:*</code>		A wide variety of EXIF data are honored, and are all prefixed with <code>Exif</code> .
<code>oiio:BitsPerSample</code>	int	The actual bits per sample in the file (may differ from <code>ImageSpec::format</code>).
<code>oiio:UnassociatedAlpha</code>	int	Nonzero if the data returned by OIIO will have "unassociated" alpha.

continues on next page

Table 2 – continued from previous page

ImageSpec Attribute	Type	TIFF header data or explanation
tiff:UnassociatedAlpha	int	Nonzero if the data in the file had “unassociated” alpha (even if using the usual convention of returning associated alpha from the read methods).

6.30 Webp

WebP is an image file format developed by Google that is intended to be an open standard for lossy-compressed images for use on the web.

Attributes

ImageSpec Attribute	Type	WebP header data or explanation
oiio:Movie	int	If nonzero, indicates that it's a multi-subimage file intended to represent an animation.
oiio:LoopCount	int	Number of times the animation should be played (0-65535, 0 stands for infinity).
webp:LoopCount	int	Deprecated synonym for oiio:LoopCount.

Configuration settings for WebP input

When opening an WebP ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration attributes are supported:

Input Configuration Attribute	Type	Meaning
oiio:ioproxy	ptr	Pointer to a Filesystem::IProxy that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for WebP output

When opening a WebP ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute	Type	Meaning
oiio:dither	int	If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy	ptr	Pointer to a Filesystem::IProxy that will handle the I/O, for example by writing to a memory buffer.

Custom I/O Overrides

WebP input and output both support the “custom I/O” feature via the special “oiio:ioproxy” attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the `set_ioproxy()` methods.

Limitations

- WebP only supports 3-channel (RGB) or 4-channel (RGBA) images and must be 8-bit unsigned integer pixel values (uint8).

6.31 Zfile

Zfile is a very simple format for writing a depth (*z*) image, originally from Pixar's PhotoRealistic RenderMan but now supported by many other renderers. It's extremely minimal, holding only a width, height, world-to-screen and camera-to-screen matrices, and uncompressed float pixels of the z-buffer. Zfile files use the file extension `.zfile`.

ImageSpec Attribute	Type	Zfile header data or explanation
<code>worldtocamera</code>	matrix	NP
<code>worldtoscreen</code>	matrix	NI

CACHED IMAGES

7.1 Image Cache Introduction and Theory of Operation

ImageCache is a utility class that allows an application to read pixels from a large number of image files while using a remarkably small amount of memory and other resources. Of course it is possible for an application to do this directly using ImageInput objects. But ImageCache offers the following advantages:

- ImageCache presents an even simpler user interface than ImageInput — the only supported operations are asking for an ImageSpec describing a subimage in the file, retrieving for a block of pixels, and locking/reading/releasing individual tiles. You refer to images by filename only; you don't need to keep track of individual file handles or ImageInput objects. You don't need to explicitly open or close files.
- The ImageCache is completely thread-safe; if multiple threads are accessing the same file, the ImageCache internals will handle all the locking and resource sharing.
- No matter how many image files you are accessing, the ImageCache will maintain a reasonable number of simultaneously-open files, automatically closing files that have not been needed recently.
- No matter how large the total pixels in all the image files you are dealing with are, the ImageCache will use only a small amount of memory. It does this by loading only the individual tiles requested, and as memory allotments are approached, automatically releasing the memory from tiles that have not been used recently.

In short, if you have an application that will need to read pixels from many large image files, you can rely on ImageCache to manage all the resources for you. It is reasonable to access thousands of image files totalling hundreds of GB of pixels, efficiently and using a memory footprint on the order of 50 MB.

Below are some simple code fragments that shows ImageCache in action:

```
#include <OpenImageIO/imagecache.h>
using namespace OIIO;

// Create an image cache and set some options
ImageCache *cache = ImageCache::create ();
cache->attribute ("max_memory_MB", 500.0f);
cache->attribute ("autotile", 64);

// Get a block of pixels from a file.
// (for brevity of this example, let's assume that 'size' is the
// number of channels times the number of pixels in the requested region)
float pixels[size];
cache->get_pixels ("file1.jpg", 0, 0, xbegin, xend, ybegin, yend,
                 zbegin, zend, TypeDesc::FLOAT, pixels);
```

(continues on next page)

(continued from previous page)

```

// Get information about a file
ImageSpec spec;
bool ok = cache->get_imagespec ("file2.exr", spec);
if (ok)
    std::cout << "resolution is " << spec.width << "x"
                << spec.height << "\n";

// Request and hold a tile, do some work with its pixels, then release
ImageCache::Tile *tile;
tile = cache->get_tile ("file2.exr", 0, 0, x, y, z);
// The tile won't be freed until we release it, so this is safe:
TypeDesc format;
void *p = cache->tile_pixels (tile, format);
// Now p points to the raw pixels of the tile, whose data format
// is given by 'format'.
cache->release_tile (tile);
// Now cache is permitted to free the tile when needed

// Note that all files were referenced by name, we never had to open
// or close any files, and all the resource and memory management
// was automatic.

ImageCache::destroy (cache);

```

7.2 ImageCache API

class **ImageCache**

Define an API to an abstract class that manages image files, caches of open file handles as well as tiles of pixels so that truly huge amounts of image data may be accessed by an application with low memory footprint.

Opaque data for performance lookups

The *ImageCache* implementation needs to maintain certain per-thread state, and some methods take an opaque *Perthread* pointer to this record. There are three options for how to deal with it:

- Don't worry about it at all: don't use the methods that want *Perthread* pointers, or always pass `nullptr` for any ``Perthread*1` arguments, and *ImageCache* will do thread-specific-pointer retrieval as necessary (though at some small cost).
- If your app already stores per-thread information of its own, you may call `get_perthread_info(nullptr)` to retrieve it for that thread, and then pass it into the functions that allow it (thus sparing them the need and expense of retrieving the thread-specific pointer). However, it is crucial that this pointer not be shared between multiple threads. In this case, the *ImageCache* manages the storage, which will automatically be released when the thread terminates.
- If your app also wants to manage the storage of the *Perthread*, it can explicitly create one with `create_perthread_info()`, pass it around, and eventually be responsible for destroying it with

`destroy_perthread_info()`. When managing the storage, the app may reuse the `Perthread` for another thread after the first is terminated, but still may not use the same `Perthread` for two threads running concurrently.

using **Perthread** = ImageCachePerThreadInfo

Define an opaque data type that allows us to have a pointer to certain per-thread information that the *ImageCache* maintains. Any given one of these should NEVER be shared between running threads.

using **ImageHandle** = ImageCacheFile

Define an opaque data type that allows us to have a handle to an image (already having its name resolved) but without exposing any internals.

Perthread ***get_perthread_info**(*Perthread* *thread_info = NULL)

Retrieve a `Perthread`, unique to the calling thread. This is a thread-specific pointer that will always return the `Perthread` for a thread, which will also be automatically destroyed when the thread terminates.

Applications that want to manage their own `Perthread` pointers (with `create_thread_info` and `destroy_thread_info`) should still call this, but passing in their managed pointer. If the passed-in `thread_info` is not NULL, it won't create a new one or retrieve a TSP, but it will do other necessary house-keeping on the `Perthread` information.

Perthread ***create_thread_info**()

Create a new `Perthread`. It is the caller's responsibility to eventually destroy it using `destroy_thread_info()`.

void **destroy_thread_info**(*Perthread* *thread_info)

Destroy a `Perthread` that was allocated by `create_thread_info()`.

ImageHandle ***get_image_handle**(*ustring* filename, *Perthread* *thread_info = nullptr, const TextureOpt *options = nullptr)

Retrieve an opaque handle for fast texture lookups, or nullptr upon failure. The filename is presumed to be UTF-8 encoded. The options, if not null, may be used to create a separate handle for certain texture option choices. (Currently unused, but reserved for the future or for alternate IC implementations.) The opaque pointer `thread_info` is thread-specific information returned by `get_perthread_info()`.

inline *ImageHandle* ***get_image_handle**(const std::wstring &filename, *Perthread* *thread_info = nullptr, const TextureOpt *options = nullptr)

Get an `ImageHandle` using a UTF-16 encoded `wstring` filename.

bool **good**(*ImageHandle* *file)

Return true if the image handle (previously returned by `get_image_handle()`) is a valid image that can be subsequently read.

ustring **filename_from_handle**(*ImageHandle* *handle)

Given a handle, return the filename for that image.

This method was added in OpenImageIO 2.3.

Controlling the cache

using **Tile** = ImageCacheTile

An opaque data type that allows us to have a pointer to a tile but without exposing any internals.

void **invalidate**(*ustring* filename, bool force = true)

Invalidate any loaded tiles or open file handles associated with the filename (UTF-8 encoded), so that any subsequent queries will be forced to re-open the file or re-load any tiles (even those that were previously loaded and would ordinarily be reused). A client might do this if, for example, they are aware that an image being held in the cache has been updated on disk. This is safe to do even if other procedures are currently holding reference-counted tile pointers from the named image, but those procedures will not get updated pixels until they release the tiles they are holding.

If **force** is true, this invalidation will happen unconditionally; if false, the file will only be invalidated if it has been changed since it was first opened by the *ImageCache*.

void **invalidate**(*ImageHandle* *file, bool force = true)

A more efficient variety of *invalidate()* for cases where you already have an *ImageHandle** for the file you want to invalidate.

void **invalidate_all**(bool force = false)

Invalidate all loaded tiles and close open file handles. This is safe to do even if other procedures are currently holding reference-counted tile pointers from the named image, but those procedures will not get updated pixels (if the images change) until they release the tiles they are holding.

If **force** is true, everything will be invalidated, no matter how wasteful it is, but if **force** is false, in actuality files will only be invalidated if their modification times have been changed since they were first opened.

void **close**(*ustring* filename)

Close any open file handles associated with a named file (UTF-8 encoded), but do not invalidate any image spec information or pixels associated with the files. A client might do this in order to release OS file handle resources, or to make it safe for other processes to modify image files on disk.

void **close_all**()

close() all files known to the cache.

Tile ***get_tile**(*ustring* filename, int subimage, int miplevel, int x, int y, int z, int chbegin = 0, int chend = -1)

Find the tile specified by an image filename (UTF-8 encoded), subimage & miplevel, the coordinates of a pixel, and optionally a channel range. An opaque pointer to the tile will be returned, or *nullptr* if no such file (or tile within the file) exists or can be read. The tile will not be purged from the cache until after *release_tile()* is called on the tile pointer the same number of times that *get_tile()* was called (reference counting). This is thread-safe! If **chend** < **chbegin**, it will retrieve a tile containing all channels in the file.

Tile ***get_tile**(*ImageHandle* *file, *Perthread* *thread_info, int subimage, int miplevel, int x, int y, int z, int chbegin = 0, int chend = -1)

A slightly more efficient variety of *get_tile()* for cases where you can use an *ImageHandle** to specify the image and optionally have a *Perthread** for the calling thread.

See also:

get_pixels()

void **release_tile**(*Tile* *tile) const

After finishing with a tile, `release_tile` will allow it to once again be purged from the tile cache if required.

TypeDesc **tile_format**(const *Tile* *tile) const

Retrieve the data type of the pixels stored in the tile, which may be different than the type of the pixels in the disk file.

ROI **tile_roi**(const *Tile* *tile) const

Retrieve the *ROI* describing the pixels and channels stored in the tile.

const void ***tile_pixels**(*Tile* *tile, *TypeDesc* &format) const

For a tile retrieved by `get_tile()`, return a pointer to the pixel data itself, and also store in `format` the data type that the pixels are internally stored in (which may be different than the data type of the pixels in the disk file). This method should only be called on a tile that has been requested by `get_tile()` but has not yet been released with `release_tile()`.

bool **add_file**(*ustring* filename, *ImageInput::Creator* creator = nullptr, const *ImageSpec* *config = nullptr, bool replace = false)

The `add_file()` call causes a file to be opened or added to the cache. There is no reason to use this method unless you are supplying a custom creator, or configuration, or both.

If `creator` is not NULL, it points to an *ImageInput::Creator* that will be used rather than the default *ImageInput::create()*, thus instead of reading from disk, creates and uses a custom *ImageInput* to generate the image. The ‘creator’ is a factory that creates the custom *ImageInput* and will be called like this:

```
std::unique_ptr<ImageInput> in (creator());
```

Once created, the *ImageCache* owns the *ImageInput* and is responsible for destroying it when done. Custom *ImageInputs* allow “procedural” images, among other things. Also, this is the method you use to set up a “writable” *ImageCache* images (perhaps with a type of *ImageInput* that’s just a stub that does as little as possible).

If `config` is not NULL, it points to an *ImageSpec* with configuration options/hints that will be passed to the underlying *ImageInput::open()* call. Thus, this can be used to ensure that the *ImageCache* opens a call with special configuration options.

This call (including any custom creator or configuration hints) will have no effect if there’s already an image by the same name in the cache. Custom creators or configurations only “work” the FIRST time a particular filename is referenced in the lifetime of the *ImageCache*. But if `replace` is true, any existing entry will be invalidated, closed and overwritten. So any subsequent access will see the new file. Existing texture handles will still be valid.

bool **add_tile**(*ustring* filename, int subimage, int miplevel, int x, int y, int z, int chbegin, int chend, *TypeDesc* format, const void *buffer, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride, bool copy = true)

Preemptively add a tile corresponding to the named image, at the given subimage, MIP level, and channel range. The tile added is the one whose corner is (x,y,z), and `buffer` points to the pixels (in the given format, with supplied strides) which will be copied and inserted into the cache and made available for future lookups. If `chend < chbegin`, it will add a tile containing the full set of channels for the image. Note that if the ‘copy’ flag is false, the data is assumed to be in some kind of persistent storage and will not be copied, nor will its pixels take up additional memory in the cache.

Creating and destroying an image cache

ImageCache is an abstract API described as a pure virtual class. The actual internal implementation is not exposed through the external API of OpenImageIO. Because of this, you cannot construct or destroy the concrete implementation, so two static methods of *ImageCache* are provided:

static std::shared_ptr<*ImageCache*> **create**(bool shared = true)

Create a *ImageCache* and return a shared pointer to it.

See also:

ImageCache::destroy

Parameters

shared – If `true`, the pointer returned will be a shared *ImageCache* (so that multiple parts of an application that request an *ImageCache* will all end up with the same one). If `shared` is `false`, a completely unique *ImageCache* will be created and returned.

Returns

A shared pointer to an *ImageCache*, which can only be freed with *ImageCache::destroy()*.

static void **destroy**(std::shared_ptr<*ImageCache*> &cache, bool teardown = false)

Release the shared_ptr to an *ImageCache*, including freeing all system resources that it holds if no one else is still using it. This is not strictly necessary to call, simply destroying the shared_ptr will do the same thing, but this call is for backward compatibility and is helpful if you want to use the teardown option.

Parameters

- **cache** – Shared pointer to the *ImageCache* to destroy.
- **teardown** – For a shared *ImageCache*, if the `teardown` parameter is `true`, it will try to truly destroy the shared cache if nobody else is still holding a reference (otherwise, it will leave it intact). This parameter has no effect if `cache` was not the single globally shared *ImageCache*.

Setting options and limits for the image cache

These are the list of attributes that can be set or queried by `attribute/getattribute`:

- `int max_open_files` : The approximate maximum number of file handles that the image cache will hold open simultaneously. This is not an iron-clad guarantee; the number of handles may momentarily exceed this by a small percentage. (Default = 100)
- `float max_memory_MB` : The approximate maximum amount of memory (measured in MB) used for the internal “tile cache.” (Default: 1024.0 MB)
- `string searchpath` : The search path for images: a colon-separated list of directories that will be searched in order for any image filename that is not specified as an absolute path. (Default: “”)
- `string plugin_searchpath` : The search path for plugins: a colon-separated list of directories that will be searched in order for any OIIO plugins, if not found in OIIO’s `lib` directory. (Default: “”)
- `int autotile, int autoscanline` : These attributes control how the image cache deals with images that are not “tiled” (i.e., are stored as scanlines).

If `autotile` is set to 0 (the default), an untiled image will be treated as if it were a single tile of the resolution of the whole image. This is simple and fast, but can lead to poor cache behavior if you are simultaneously accessing many large untiled images.

If `autotile` is nonzero (e.g., 64 is a good recommended value), any untiled images will be read and cached as if they were constructed in tiles of size:

```
- `autotile * autotile`
    if `autoscanline` is 0
- `width * autotile`
    if `autoscanline` is nonzero.
```

In both cases, this should lead more efficient caching. The `autoscanline` determines whether the “virtual tiles” in the cache are square (if `autoscanline` is 0, the default) or if they will be as wide as the image (but only `autotile` scanlines high). You should try in your application to see which leads to higher performance.

- `int autoscanline` : autotile using full width tiles
- `int automip` : If 0 (the default), an untiled single-subimage file will only be able to utilize that single subimage. If nonzero, any untiled, single-subimage (un-MIP-mapped) images will have lower-resolution MIP-map levels generated on-demand if pixels are requested from the lower-res subimages (that don’t really exist). Essentially this makes the *ImageCache* pretend that the file is MIP-mapped even if it isn’t.
- `int accept_untiled` : When nonzero, *ImageCache* accepts untiled images as usual. When zero, *ImageCache* will reject untiled images with an error condition, as if the file could not be properly read. This is sometimes helpful for applications that want to enforce use of tiled images only. (default=1)
- `int accept_unmipped` : When nonzero, *ImageCache* accepts un-MIPmapped images as usual. When set to zero, *ImageCache* will reject un-MIPmapped images with an error condition, as if the file could not be properly read. This is sometimes helpful for applications that want to enforce use of MIP-mapped images only. (Default: 1)
- `int statistics:level` : verbosity of statistics auto-printed.
- `int forcefloat` : If set to nonzero, all image tiles will be converted to `float` type when stored in the image cache. This can be helpful especially for users of `ImageBuf` who want to simplify their image manipulations to only need to consider `float` data. The default is zero, meaning that image pixels are not forced to be `float` when in cache.
- `int failure_retries` : When an image file is opened or a tile/scanline is read but a file error occurs, if this attribute is nonzero, it will try the operation again up to this many times before giving up and reporting a failure. Setting this to a small nonzero number (like 3) may help make an application more robust to occasional spurious networking or other glitches that would otherwise cause the entire long-running application to fail upon a single transient error. (Default: 0)
- `int deduplicate` : When nonzero, the *ImageCache* will notice duplicate images under different names if their headers contain a SHA-1 fingerprint (as is done with `maketx`-produced textures) and handle them more efficiently by avoiding redundant reads. The default is 1 (de-duplication turned on). The only reason to set it to 0 is if you specifically want to disable the de-duplication optimization.
- `int max_open_files_strict` : If nonzero, work harder to make sure that we have smaller possible overages to the max open files limit. (Default: 0)
- `string substitute_image` : When set to anything other than the empty string, the *ImageCache* will use the named image in place of *all* other images. This allows you to run an app using OIIO and (if you can manage to get this option set) automatically substitute a grid, zone plate, or other special debugging image for all image/texture use.

- `int unassociatedalpha` : When nonzero, will request that image format readers try to leave input images with unassociated alpha as they are, rather than automatically converting to associated alpha upon reading the pixels. The default is 0, meaning that the automatic conversion will take place.
- `int max_errors_per_file` : The maximum number of errors that will be printed for each file. The default is 100. If your output is cluttered with error messages and after the first few for each file you aren't getting any helpful additional information, this can cut down on the clutter and the runtime. (default: 100)
- `int trust_file_extensions` : When nonzero, assume that the file extensions of any texture requests correctly indicates the file format (when enabled, this reduces the number of file opens, at the expense of not being able to open files if their format do not actually match their filename extension). Default: 0
- `string colorspace` : The working colorspace of the texture system. Default: none.
- `string colorconfig` : Name of the OCIO config to use. Default: "" (meaning to use the default color config).
- `string options` This catch-all is simply a comma-separated list of `name=value` settings of named options, which will be parsed and individually set. Example:

```
ic->attribute ("options", "max_memory_MB=512.0,autotile=1");
```

Note that if an option takes a string value that must itself contain a comma, it is permissible to enclose the value in either single (`'`) or double (`"`) quotes.

Read-only attributes

Additionally, there are some read-only attributes that can be queried with `getattribute()` even though they cannot be set via `attribute()`:

- `int total_files` : The total number of unique file names referenced by calls to the *ImageCache*.
- `string[] all_filenames` : An array that will be filled with the list of the names of all files referenced by calls to the *ImageCache*. (The array is of `ustring` or `char*`.)
- `int64 stat:cache_footprint` : Total bytes used by image cache.
- `int64 stat:cache_memory_used` : Total bytes used by tile cache.
- `int stat:tiles_created`, `int stat:tiles_current`, `int stat:tiles_peak` : Total times created, still allocated (at the time of the query), and the peak number of tiles in memory at any time.
- `int stat:open_files_created`, `int stat:open_files_current`, `int stat:open_files_peak` : Total number of times a file was opened, number still opened (at the time of the query), and the peak number of files opened at any time.
- `int stat:find_tile_calls` : Number of times a filename was looked up in the file cache.
- `int64 stat:image_size` : Total size (uncompressed bytes of pixel data) of all images referenced by the *ImageCache*. (Note: Prior to 1.7, this was called `stat:files_totalsize`.)
- `int64 stat:file_size` : Total size of all files (as on disk, possibly compressed) of all images referenced by the *ImageCache*.
- `int64 stat:bytes_read` : Total size (uncompressed bytes of pixel data) read.
- `int stat:unique_files` : Number of unique files opened.
- `float stat:fileio_time` : Total I/O-related time (seconds).
- `float stat:fileopen_time` : I/O time related to opening and reading headers (but not pixel I/O).

- `float stat:file_locking_time`: Total time (across all threads) that threads blocked waiting for access to the file data structures.
- `float stat:tile_locking_time`: Total time (across all threads) that threads blocked waiting for access to the tile cache data structures.
- `float stat:find_file_time`: Total time (across all threads) that threads spent looking up files by name.
- `float stat:find_tile_time`: Total time (across all threads) that threads spent looking up individual tiles.

The following member functions of *ImageCache* allow you to set (and in some cases retrieve) options that control the overall behavior of the image cache:

bool **attribute**(string_view name, *TypeDesc* type, const void *val)

Set a named attribute (i.e., a property or option) of the *ImageCache*.

Example:

```
ImageCache *ic;
...
int maxfiles = 50;
ic->attribute ("max_open_files", TypeDesc::INT, &maxfiles);

const char *path = "/my/path";
ic->attribute ("searchpath", TypeDesc::STRING, &path);

// There are specialized versions for setting a single int,
// float, or string without needing types or pointers:
ic->attribute ("max_open_files", 50);
ic->attribute ("max_memory_MB", 4000.0f);
ic->attribute ("searchpath", "/my/path");
```

Note: When passing a string, you need to pass a pointer to the `char*`, not a pointer to the first character. (Rationale: for an `int` attribute, you pass the address of the `int`. So for a string, which is a `char*`, you need to pass the address of the string, i.e., a `char**`).

Parameters

- **name** – Name of the attribute to set.
- **type** – *TypeDesc* describing the type of the attribute.
- **val** – Pointer to the value data.

Returns

true if the name and type were recognized and the attribute was set, or false upon failure (including it being an unrecognized attribute or not of the correct type).

inline bool **attribute**(string_view name, int val)

Specialized *attribute()* for setting a single `int` value.

inline bool **attribute**(string_view name, float val)

Specialized *attribute()* for setting a single `float` value.

inline bool **attribute**(string_view name, string_view val)

Specialized *attribute()* for setting a single string value.

bool **getattribute**(string_view name, *TypeDesc* type, void *val) const

Get the named attribute, store it in *val. All of the attributes that may be set with the *attribute()* call may also be queried with *getattribute()*.

Examples:

```
ImageCache *ic;
...
int maxfiles;
ic->getattribute ("max_open_files", TypeDesc::INT, &maxfiles);

const char *path;
ic->getattribute ("searchpath", TypeDesc::STRING, &path);

// There are specialized versions for retrieving a single int,
// float, or string without needing types or pointers:
int maxfiles;
ic->getattribute ("max_open_files", maxfiles);
const char *path;
ic->getattribute ("searchpath", &path);
```

Note: When retrieving a string, you need to pass a pointer to the *char**, not a pointer to the first character. Also, the *char** will end up pointing to characters owned by the *ImageCache*; the caller does not need to ever free the memory that contains the characters.

Parameters

- **name** – Name of the attribute to retrieve.
- **type** – *TypeDesc* describing the type of the attribute.
- **val** – Pointer where the attribute value should be stored.

Returns

true if the name and type were recognized and the attribute was retrieved, or false upon failure (including it being an unrecognized attribute or not of the correct type).

inline bool **getattribute**(string_view name, int &val) const

Specialized *attribute()* for retrieving a single int value.

inline bool **getattribute**(string_view name, float &val) const

Specialized *attribute()* for retrieving a single float value.

inline bool **getattribute**(string_view name, char **val) const

Specialized *attribute()* for retrieving a single string value as a *char**.

inline bool **getattribute**(string_view name, std::string &val) const

Specialized *attribute()* for retrieving a single string value as a *std::string*.

TypeDesc **getattributetype**(string_view name) const

If the named attribute is known, return its data type. If no such attribute exists, return *TypeUnknown*.

This was added in version 2.5.

Getting information about images

`std::string resolve_filename(const std::string &filename) const`

Given possibly-relative filename (UTF-8 encoded), resolve it and use the true path to the file, with search-path logic applied.

`bool get_image_info(ustring filename, int subimage, int miplevel, ustring dataname, TypeDesc datatype, void *data)`

Get information or metadata about the named image and store it in *data.

Data names may include any of the following:

- "exists" : Stores the value 1 (as an int) if the file exists and is an image format that OpenImageIO can read, or 0 if the file does not exist, or could not be properly read as an image. Note that unlike all other queries, this query will “succeed” (return true) even if the file does not exist.
- "udim" : Stores the value 1 (as an int) if the file is a “virtual UDIM” or texture atlas file (as described in `ref:sec-texturesys-udim`) or 0 otherwise.
- "subimages" : The number of subimages in the file, as an int.
- "resolution" : The resolution of the image file, which is an array of 2 integers (described as `TypeDesc(INT,2)`).
- "miplevels" : The number of MIPmap levels for the specified subimage (an integer).
- "texturetype" : A string describing the type of texture of the given file, which describes how the texture may be used (also which texture API call is probably the right one for it). This currently may return one of: "unknown", "Plain Texture", "Volume Texture", "Shadow", or "Environment".
- "textureformat" : A string describing the format of the given file, which describes the kind of texture stored in the file. This currently may return one of: "unknown", "Plain Texture", "Volume Texture", "Shadow", "CubeFace Shadow", "Volume Shadow", "LatLong Environment", or "CubeFace Environment". Note that there are several kinds of shadows and environment maps, all accessible through the same API calls.
- "channels" : The number of color channels in the file (an int).
- "format" : The native data format of the pixels in the file (an integer, giving the `TypeDesc::BASETYPE` of the data). Note that this is not necessarily the same as the data format stored in the image cache.
- "cachedformat" : The native data format of the pixels as stored in the image cache (an integer, giving the `TypeDesc::BASETYPE` of the data). Note that this is not necessarily the same as the native data format of the file.
- "datawindow" : Returns the pixel data window of the image, which is either an array of 4 integers (returning xmin, ymin, xmax, ymax) or an array of 6 integers (returning xmin, ymin, zmin, xmax, ymax, zmax). The z values may be useful for 3D/volumetric images; for 2D images they will be 0).
- "displaywindow" : Returns the display (a.k.a. “full”) window of the image, which is either an array of 4 integers (returning xmin, ymin, xmax, ymax) or an array of 6 integers (returning xmin, ymin, zmin, xmax, ymax, zmax). The z values may be useful for 3D/volumetric images; for 2D images they will be 0).
- "worldtocamera" : The viewing matrix, which is a 4x4 matrix (an `Imath::M44f`, described as `TypeDesc(FLOAT,MATRIX)`), giving the world-to-camera 3D transformation matrix that was used when the image was created. Generally, only rendered images will have this.

- "worldtoscreen" : The projection matrix, which is a 4x4 matrix (an `Imath::M44f`, described as `TypeDesc(FLOAT,MATRIX)`), giving the matrix that projected points from world space into a 2D screen coordinate system where x and y range from -1 to +1. Generally, only rendered images will have this.
- "worldtoNDC" : The projection matrix, which is a 4x4 matrix (an `Imath::M44f`, described as `TypeDesc(FLOAT,MATRIX)`), giving the matrix that projected points from world space into a 2D NDC coordinate system where x and y range from 0 to +1. Generally, only rendered images will have this.
- "averagecolor" : If available in the metadata (generally only for files that have been processed by `maketx`), this will return the average color of the texture (into an array of `float`).
- "averagealpha" : If available in the metadata (generally only for files that have been processed by `maketx`), this will return the average alpha value of the texture (into a `float`).
- "constantcolor" : If the metadata (generally only for files that have been processed by `maketx`) indicates that the texture has the same values for all pixels in the texture, this will retrieve the constant color of the texture (into an array of floats). A non-constant image (or one that does not have the special metadata tag identifying it as a constant texture) will fail this query (return `false`).
- "constantalpha" : If the metadata indicates that the texture has the same values for all pixels in the texture, this will retrieve the constant alpha value of the texture (into a `float`). A non-constant image (or one that does not have the special metadata tag identifying it as a constant texture) will fail this query (return `false`).
- "stat:tilesread" : Number of tiles read from this file (`int64`).
- "stat:bytesread" : Number of bytes of uncompressed pixel data read from this file (`int64`).
- "stat:redundant_tiles" : Number of times a tile was read, where the same tile had been read before. (`int64`).
- "stat:redundant_bytesread" : Number of bytes (of uncompressed pixel data) in tiles that were read redundantly. (`int64`).
- "stat:redundant_tilesread" : Number of tiles read from this file (`int`).
- "stat:image_size" : Size of the uncompressed image pixel data of this image, in bytes (`int64`).
- "stat:file_size" : Size of the disk file (possibly compressed) for this image, in bytes (`int64`).
- "stat:timesopened" : Number of times this file was opened (`int`).
- "stat:iotime" : Time (in seconds) spent on all I/O for this file (`float`).
- "stat:mipsused" : Stores 1 if any MIP levels beyond the highest resolution were accessed, otherwise 0. (`int`)
- "stat:is_duplicate" : Stores 1 if this file was a duplicate of another image, otherwise 0. (`int`)
- *Anything else* : For all other data names, the the metadata of the image file will be searched for an item that matches both the name and data type.

Parameters

- **filename** – The name of the image, as a UTF-8 encoded ustring.
- **subimage/miplevel** – The subimage and MIP level to query.
- **dataname** – The name of the metadata to retrieve.
- **datatype** – *TypeDesc* describing the data type.

- **data** – Pointer to the caller-owned memory where the values should be stored. It is the caller's responsibility to ensure that data points to a large enough storage area to accommodate the datatype requested.

Returns

true if `get_image_info()` is able to find the requested dataname for the image and it matched the requested datatype. If the requested data was not found or was not of the right data type, return false. Except for the "exists" query, a file that does not exist or could not be read properly as an image also constitutes a query failure that will return false.

```
bool get_image_info(ImageHandle *file, Perthread *thread_info, int subimage, int miplevel, ustring
                    dataname, TypeDesc datatype, void *data)
```

A more efficient variety of `get_image_info()` for cases where you can use an `ImageHandle*` to specify the image and optionally have a `Perthread*` for the calling thread.

```
bool get_imagespec(ustring filename, ImageSpec &spec, int subimage = 0)
```

Copy the *ImageSpec* that describes the named image file.

Note that the spec returned describes the file as it exists in the file, at the base (highest-resolution) MIP level of that subimage. Certain aspects of the in-cache representation may differ from the file (due to *ImageCache* implementation strategy or options like "forcefloat" or "autotile"). If you really need to know the in-cache data type, tile size, or how the resolution or tiling changes on a particular MIP level, you should use `get_cache_dimensions()`.

Parameters

- **filename** – The name of the image, as a UTF-8 encoded *ustring*.
- **spec** – *ImageSpec* into which will be copied the spec for the requested image.
- **subimage** – The subimage to query.

Returns

true upon success, false upon failure failure (such as being unable to find, open, or read the file, or if it does not contain the designated subimage).

```
bool get_imagespec(ImageHandle *file, Perthread *thread_info, ImageSpec &spec, int subimage = 0)
```

A more efficient variety of `get_imagespec()` for cases where you can use an `ImageHandle*` to specify the image and optionally have a `Perthread*` for the calling thread.

```
inline bool get_imagespec(ustring filename, ImageSpec &spec, int subimage, int miplevel, bool native =
                        false)
```

DEPRECATED old API. Note that the miplevel and native parameters are ignored: it will always get the native spec of miplevel 0. We recommend switching to the new API.

```
const ImageSpec *imagespec(ustring filename, int subimage = 0)
```

Return a pointer to an *ImageSpec* that describes the named image file. If the file is found and is an image format that can be read, otherwise return `nullptr`.

This method is much more efficient than `get_imagespec()`, since it just returns a pointer to the spec held internally by the *ImageCache* (rather than copying the spec to the user's memory). However, the caller must beware that the pointer is only valid as long as nobody (even other threads) calls `invalidate()` on the file, or `invalidate_all()`, or destroys the *ImageCache*.

Note that the spec returned describes the file as it exists in the file, at the base (highest-resolution) MIP level of that subimage. Certain aspects of the in-cache representation may differ from the file (due to *ImageCache* implementation strategy or options like "forcefloat" or "autotile"). If you really need to know the in-cache data type, tile size, or how the resolution or tiling changes on a particular MIP level, you should use `get_cache_dimensions()`.

Parameters

- **filename** – The name of the image, as a UTF-8 encoded ustring.
- **subimage** – The subimage to query.

Returns

A pointer to the spec, if the image is found and able to be opened and read by an available image format plugin, and the designated subimage exists.

```
const ImageSpec *imagespec(ImageHandle *file, Perthread *thread_info, int subimage = 0)
```

A more efficient variety of *imagespec()* for cases where you can use an *ImageHandle** to specify the image and optionally have a *Perthread** for the calling thread.

```
inline const ImageSpec *imagespec(ustring filename, int subimage, int miplevel, bool native = false)
```

DEPRECATED old API. Note that the miplevel and native parameters are ignored: it will always get the native spec of miplevel 0. We recommend switching to the new API.

```
bool get_cache_dimensions(ustring filename, ImageSpec &spec, int subimage = 0, int miplevel = 0)
```

Copy the image dimensions (x, y, z, width, height, depth, full*, nchannels, format) and data types that describes the named image cache file for the specified subimage and miplevel. It does *not* copy arbitrary named metadata or channel names (thus, for an *ImageSpec* with lots of metadata, it is much less expensive than copying the whole thing with *operator=()*). The associated metadata and channels names can be retrieved with *imagespec()* or *get_imagespec*.

Parameters

- **filename** – The name of the image, as a UTF-8 encoded ustring.
- **spec** – *ImageSpec* into which will be copied the dimensions for the requested image.
- **subimage/miplevel** – The subimage and mip level to query.

Returns

true upon success, false upon failure failure (such as being unable to find, open, or read the file, or if it does not contain the designated subimage or mip level).

```
bool get_cache_dimensions(ImageHandle *file, Perthread *thread_info, ImageSpec &spec, int subimage = 0, int miplevel = 0)
```

A more efficient variety of *get_cache_dimensions()* for cases where you can use an *ImageHandle** to specify the image and optionally have a *Perthread** for the calling thread.

```
bool get_thumbnail(ustring filename, ImageBuf &thumbnail, int subimage = 0)
```

Copy into thumbnail any associated thumbnail associated with this image (for the first subimage by default, or as set by subimage).

Parameters

- **filename** – The name of the image, as a UTF-8 encoded ustring.
- **thumbnail** – *ImageBuf* into which will be copied the thumbnail, if it exists. If no thumbnail can be retrieved, thumb will be reset to an uninitialized (empty) *ImageBuf*.
- **subimage** – The subimage to query.

Returns

true upon success, false upon failure failure (such as being unable to find, open, or read the file, or if it does not contain a thumbnail).

```
bool get_thumbnail(ImageHandle *file, Perthread *thread_info, ImageBuf &thumbnail, int subimage = 0)
```

A more efficient variety of *get_thumbnail()* for cases where you can use an *ImageHandle** to specify the image and optionally have a *Perthread** for the calling thread.

Getting Pixels

```
bool get_pixels(ustring filename, int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int
                zbegin, int zend, int chbegin, int chend, TypeDesc format, void *result, stride_t xstride =
                AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride, int cache_chbegin =
                0, int cache_chend = -1)
```

For an image specified by name, retrieve the rectangle of pixels from the designated subimage and MIP level, storing the pixel values beginning at the address specified by `result` and with the given strides. The pixel values will be converted to the data type specified by `format`. The rectangular region to be retrieved includes `begin` but does not include `end` (much like STL `begin/end` usage). Requested pixels that are not part of the valid pixel data region of the image file will be filled with zero values.

Parameters

- **filename** – The name of the image, as a UTF-8 encoded *ustring*.
- **subimage/miplevel** – The subimage and MIP level to retrieve pixels from.
- **xbegin/xend/ybegin/yend/zbegin/zend** – The range of pixels to retrieve. The pixels retrieved include the `begin` value but not the `end` value (much like STL `begin/end` usage).
- **chbegin/chend** – Channel range to retrieve. To retrieve all channels, use `chbegin = 0`, `chend = nchannels`.
- **format** – *TypeDesc* describing the data type of the values you want to retrieve into `result`. The pixel values will be converted to this type regardless of how they were stored in the file.
- **result** – Pointer to the memory where the pixel values should be stored. It is up to the caller to ensure that `result` points to an area of memory big enough to accommodate the requested rectangle (taking into consideration its dimensions, number of channels, and data format).
- **xstride/ystride/zstride** – The number of bytes between the beginning of successive pixels, scanlines, and image planes, respectively. Any stride values set to `AutoStride` will be assumed to indicate a contiguous data layout in that dimension.
- **cache_chbegin/cache_chend** – These parameters can be used to tell the *ImageCache* to read and cache a subset of channels (if not specified or if they denote a non-positive range, all the channels of the file will be stored in the cached tile).

Returns

`true` for success, `false` for failure.

```
bool get_pixels(ImageHandle *file, Perthread *thread_info, int subimage, int miplevel, int xbegin, int xend,
                int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, TypeDesc format, void
                *result, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride =
                AutoStride, int cache_chbegin = 0, int cache_chend = -1)
```

A more efficient variety of `get_pixels()` for cases where you can use an *ImageHandle** to specify the image and optionally have a *Perthread** for the calling thread.

```
bool get_pixels(ustring filename, int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int
                zbegin, int zend, TypeDesc format, void *result)
```

A simplified `get_pixels()` where all channels are retrieved, strides are assumed to be contiguous.

```
bool get_pixels(ImageHandle *file, Perthread *thread_info, int subimage, int miplevel, int xbegin, int xend,
                int ybegin, int yend, int zbegin, int zend, TypeDesc format, void *result)
```

A more efficient variety of `get_pixels()` for cases where you can use an *ImageHandle** to specify the image and optionally have a *Perthread** for the calling thread.

Errors and statistics

bool **has_error**() const

Is there a pending error message waiting to be retrieved?

std::string **geterror**(bool clear = true) const

Return the text of all pending error messages issued against this *ImageCache*, and clear the pending error message unless `clear` is false. If no error message is pending, it will return an empty string.

std::string **getstats**(int level = 1) const

Returns a big string containing useful statistics about the *ImageCache* operations, suitable for saving to a file or outputting to the terminal. The `level` indicates the amount of detail in the statistics, with higher numbers (up to a maximum of 5) yielding more and more esoteric information.

void **reset_stats**()

Reset most statistics to be as they were with a fresh *ImageCache*. Caveat emptor: this does not flush the cache itself, so the resulting statistics from the next set of texture requests will not match the number of tile reads, etc., that would have resulted from a new *ImageCache*.

TEXTURE ACCESS: TEXTURESYSYSTEM

8.1 Texture System Introduction and Theory of Operation

Coming soon. FIXME

8.2 Helper Classes

8.2.1 Imath

The texture functionality of OpenImageIO uses the excellent open source Imath types when it requires 3D vectors and transformation matrixes. Specifically, we use `Imath::V3f` for 3D positions and directions, and `Imath::M44f` for 4x4 transformation matrices. To use these yourself, we recommend that you:

```
// If using Imath 3.x:
#include <Imath/ImathVec.h>
#include <Imath/ImathMatrix.h>

// OR, if using OpenEXR 2.x, before Imath split off:
#include <OpenEXR/ImathVec.h>
#include <OpenEXR/ImathMatrix.h>
```

Please refer to the Imath documentation and header files for more complete information about use of these types in your own application. However, note that you are not strictly required to use these classes in your application — `Imath::V3f` has a memory layout identical to `float[3]` and `Imath::M44f` has a memory layout identical to `float[16]`, so as long as your own internal vectors and matrices have the same memory layout, it's ok to just cast pointers to them when passing as arguments to TextureSystem methods.

8.2.2 TextureOpt

TextureOpt is a structure that holds many options controlling single-point texture lookups. Because each texture lookup API call takes a reference to a TextureOpt, the call signatures remain uncluttered rather than having an ever-growing list of parameters, most of which will never vary from their defaults. Here is a brief description of the data members of a TextureOpt structure:

- `int firstchannel` : The beginning channel for the lookup. For example, to retrieve just the blue channel, you should have `firstchannel = 2` while passing `nchannels = 1` to the appropriate texture function.
- `int subimage`, `ustring subimagename` : Specifies the subimage or face within the file to use for the texture lookup. If `subimagename` is set (it defaults to the empty string), it will try to use the subimage that had a matching

metadata "oiio:subimagename", otherwise the integer `subimage` will be used (which defaults to 0, i.e., the first/default subimage). Nonzero subimage indices only make sense for a texture file that supports subimages (like TIFF or multi-part OpenEXR) or separate images per face (such as Ptex). This will be ignored if the file does not have multiple subimages or separate per-face textures.

- `Wrap` `swrap`, `twrap` : Specify the *wrap mode* for 2D texture lookups (and 3D volume texture lookups, using the additional `rwrap` field). These fields are ignored for shadow and environment lookups. These specify what happens when texture coordinates are found to be outside the usual `[0,1]` range over which the texture is defined. `Wrap` is an enumerated type that may take on any of the following values:
 - `WrapBlack` : The texture is black outside the `[0,1]` range.
 - `WrapClamp` : The texture coordinates will be clamped to `[0,1]`, i.e., the value outside `[0,1]` will be the same as the color at the nearest point on the border.
 - `WrapPeriodic` : The texture is periodic, i.e., wraps back to 0 after going past 1.
 - `WrapMirror` : The texture presents a mirror image at the edges, i.e., the coordinates go from 0 to 1, then back down to 0, then back up to 1, etc.
 - `WrapDefault` : Use whatever wrap might be specified in the texture file itself, or some other suitable default (caveat emptor).

The wrap mode does not need to be identical in the `s` and `t` directions.

- `float` `swidth`, `twidth` : For each direction, gives a multiplier for the derivatives. Note that a width of 0 indicates a point sampled lookup (assuming that blur is also zero). The default width is 1, indicating that the derivatives should guide the amount of blur applied to the texture filtering (not counting any additional *blur* specified).
- `float` `sblur`, `tblur` : For each direction, specifies an additional amount of pre-blur to apply to the texture (*after* derivatives are taken into account), expressed as a portion of the width of the texture. In other words, `blur = 0.1` means that the texture lookup should act as if the texture was pre-blurred with a filter kernel with a width 1/10 the size of the full image. The default blur amount is 0, indicating a sharp texture lookup.
- `float` `fill` : Specifies the value that will be used for any color channels that are requested but not found in the file. For example, if you perform a 4-channel lookup on a 3-channel texture, the last channel will get the fill value. (Note: this behavior is affected by the "gray_to_rgb" attribute described in the Section about `TextureSystem` attributes.
- `const float*` `missingcolor` : If not NULL, indicates that a missing or broken texture should *not* be treated as an error, but rather will simply return the supplied color as the texture lookup color and `texture()` will return `true`. If the `missingcolor` field is left at its default (a NULL pointer), a missing or broken texture will be treated as an error and `texture()` will return `false`. Note: When not NULL, the data must point to `nchannels` contiguous floats.
- `Wrap` `rwrap`, `float` `rblur`, `rwidth` : Specifies wrap, blur, and width for the third component of 3D volume texture lookups. These are not used for 2D texture or environment lookups.
- `MipMode` `mipmode` : Determines if/how MIP-maps are used:
 - `MipModeDefault` : The default high-quality lookup (same as Aniso).
 - `MipModeNoMIP` : Just use highest-res image, no MIP mapping
 - `MipModeOneLevel` : Use just one mipmap level
 - `MipModeTrilinear` : Use two MIPmap levels (trilinear)
 - `MipModeAniso` : Use two MIPmap levels w/ anisotropic
- `InterpMode` `interpmode` : Determines how we sample within a mipmap level:
 - `InterpClosest` : Force closest texel.

- `InterpBilinear` : Force bilinear lookup within a mip level.
- `InterpBicubic` : Force cubic lookup within a mip level.
- `InterpSmartBicubic` : Bicubic when maxifying, else bilinear (default).
- `int anisotropic` : Maximum anisotropic ratio (default: 32).
- `bool conservative_filter` : When true (the default), filters conservatively in a way that chooses to sometimes over-blur rather than alias.

8.3 TextureSystem API

class `TextureSystem`

Define an API to an abstract class that manages texture files, caches of open file handles as well as tiles of texels so that truly huge amounts of texture may be accessed by an application with low memory footprint, and ways to perform antialiased texture, shadow map, and environment map lookups.

Creating and destroying a texture system

TextureSystem is an abstract API described as a pure virtual class. The actual internal implementation is not exposed through the external API of OpenImageIO. Because of this, you cannot construct or destroy the concrete implementation, so two static methods of *TextureSystem* are provided:

```
static std::shared_ptr<TextureSystem> create(bool shared = true, std::shared_ptr<ImageCache> imagecache = {})
```

Create a *TextureSystem* and return a shared pointer to it.

See also:

TextureSystem::destroy

Parameters

- **shared** – If `shared` is `true`, the pointer returned will be a shared *TextureSystem*, (so that multiple parts of an application that request a *TextureSystem* will all end up with the same one, and the same underlying *ImageCache*). If `shared` is `false`, a completely unique *TextureCache* will be created and returned.
- **imagecache** – If `shared` is `false` and `imagecache` is not empty, the *TextureSystem* will use this as its underlying *ImageCache*. In that case, it is the caller who is responsible for eventually freeing the *ImageCache* after the *TextureSystem* is destroyed. If `shared` is `false` and `imagecache` is empty, then a custom *ImageCache* will be created, owned by the *TextureSystem*, and automatically freed when the TS destroys. If `shared` is `true`, this parameter will not be used, since the global shared *TextureSystem* uses the global shared *ImageCache*.

Returns

A shared pointer to a *TextureSystem* which will be destroyed only when the last `shared_ptr` to it is destroyed.

static void **destroy**(std::shared_ptr<*TextureSystem*> &ts, bool teardown_imagecache = false)

Release the shared_ptr to a *TextureSystem*, including freeing all system resources that it holds if no one else is still using it. This is not strictly necessary to call, simply destroying the shared_ptr will do the same thing, but this call is for backward compatibility and is helpful if you want to use the `teardown_imagecache` option.

Parameters

- **ts** – Shared pointer to the *TextureSystem* to destroy.
- **teardown_imagecache** – For a shared *TextureSystem*, if the `teardown_imagecache` parameter is `true`, it will try to truly destroy the shared cache if nobody else is still holding a reference (otherwise, it will leave it intact). This parameter has no effect if **ts** was not the single globally shared *TextureSystem*.

Setting options and limits for the texture system

These are the list of attributes that can be set or queried by `attribute/getattribute`:

All attributes ordinarily recognized by *ImageCache* are accepted and passed through to the underlying *ImageCache*. These include:

- `int max_open_files` : Maximum number of file handles held open.
- `float max_memory_MB` : Maximum tile cache size, in MB.
- `string searchpath` : Colon-separated search path for texture files.
- `string plugin_searchpath` : Colon-separated search path for plugins.
- `int autotile` : If >0, tile size to emulate for non-tiled images.
- `int autoscanline` : If nonzero, autotile using full width tiles.
- `int automip` : If nonzero, emulate mipmap on the fly.
- `int accept_untiled` : If nonzero, accept untiled images.
- `int accept_unmipped` : If nonzero, accept unmipped images.
- `int failure_retries` : How many times to retry a read failure.
- `int deduplicate` : If nonzero, detect duplicate textures (default=1).
- `int max_open_files_strict` : If nonzero, work harder to make sure that we have smaller possible overages to the max open files limit.
- `string substitute_image` : If supplied, an image to substitute for all texture references.
- `int max_errors_per_file` : Limits how many errors to issue for each file. (default: 100)
- `string colorspace` : The working colorspace of the texture system.
- `string colorconfig` : Name of the OCIO config to use (default: "").

Texture-specific settings:

- `matrix44 worldtocommon / matrix44 commontoworld` : The 4x4 matrices that provide the spatial transformation from “world” to a “common” coordinate system and back. This is mainly used for shadow map lookups, in which the shadow map itself encodes the world coordinate system, but positions passed to `shadow()` are expressed in “common” coordinates. You do not need to set `commontoworld` and `worldtocommon` separately; just setting either one will implicitly set the other, since each is the inverse of the other.

- **int gray_to_rgb** : If set to nonzero, texture lookups of single-channel (grayscale) images will replicate the sole channel's values into the next two channels, making it behave like an RGB image that happens to have all three channels with identical pixel values. (Channels beyond the third will get the "fill" value.) The default value of zero means that all missing channels will get the "fill" color.
- **int max_tile_channels** : The maximum number of color channels in a texture file for which all channels will be loaded as a single cached tile. Files with more than this number of color channels will have only the requested subset loaded, in order to save cache space (but at the possible wasted expense of separate tiles that overlap their channel ranges). The default is 5.
- **int max_mip_res** : **NEW 2.1** Sets the maximum MIP-map resolution for filtered texture lookups. The MIP levels used will be clamped to those having fewer than this number of pixels in each dimension. This can be helpful as a way to limit disk I/O when doing fast preview renders (with the tradeoff that you may see some texture more blurry than they would ideally be). The default is $1 \ll 30$, a value so large that no such clamping will be performed.
- **string latlong_up** : The default "up" direction for latlong environment maps (only applies if the map itself doesn't specify a format or is in a format that explicitly requires a particular orientation). The default is "y". (Currently any other value will result in *z* being "up.")
- **int flip_t** : If nonzero, *t* coordinates will be flipped $1-t$ for all texture lookups. The default is 0.
- **int stochastic** : Bit field determining how to use stochastic sampling for `MipModeStochasticAniso` and/or `MipModeStochasticTrilinear`. Bit 1 = sample MIP level, bit 2 = sample anisotropy (default=0).
- **string options** This catch-all is simply a comma-separated list of `name=value` settings of named options, which will be parsed and individually set.

```
ic->attribute ("options", "max_memory_MB=512.0,autotile=1");
```

Note that if an option takes a string value that must itself contain a comma, it is permissible to enclose the value in either single or double quotes.

Read-only attributes

Additionally, there are some read-only attributes that can be queried with `getattribute()` even though they cannot be set via `attribute()`:

The following member functions of `TextureSystem` allow you to set (and in some cases retrieve) options that control the overall behavior of the texture system:

bool **attribute**(string_view name, *TypeDesc* type, const void *val)

Set a named attribute (i.e., a property or option) of the `TextureSystem`.

Example:

```
TextureSystem *ts;
...
int maxfiles = 50;
ts->attribute ("max_open_files", TypeDesc::INT, &maxfiles);

const char *path = "/my/path";
ts->attribute ("searchpath", TypeDesc::STRING, &path);

// There are specialized versions for retrieving a single int,
// float, or string without needing types or pointers:
ts->getattribute ("max_open_files", 50);
ic->attribute ("max_memory_MB", 4000.0f);
ic->attribute ("searchpath", "/my/path");
```

Note: When passing a string, you need to pass a pointer to the `char*`, not a pointer to the first character. (Rationale: for an `int` attribute, you pass the address of the `int`. So for a string, which is a `char*`, you need to pass the address of the string, i.e., a `char**`).

Parameters

- **name** – Name of the attribute to set.
- **type** – *TypeDesc* describing the type of the attribute.
- **val** – Pointer to the value data.

Returns

true if the name and type were recognized and the attribute was set, or false upon failure (including it being an unrecognized attribute or not of the correct type).

inline bool **attribute**(string_view name, int val)

Specialized *attribute()* for setting a single `int` value.

inline bool **attribute**(string_view name, float val)

Specialized *attribute()* for setting a single `float` value.

inline bool **attribute**(string_view name, string_view val)

Specialized *attribute()* for setting a single string value.

bool **getattribute**(string_view name, *TypeDesc* type, void *val) const

Get the named attribute of the texture system, store it in `*val`. All of the attributes that may be set with the *attribute()* call may also be queried with *getattribute()*.

Examples:

```
TextureSystem *ic;
...
int maxfiles;
ts->getattribute ("max_open_files", TypeDesc::INT, &maxfiles);

const char *path;
ts->getattribute ("searchpath", TypeDesc::STRING, &path);

// There are specialized versions for retrieving a single int,
// float, or string without needing types or pointers:
int maxfiles;
ts->getattribute ("max_open_files", maxfiles);
const char *path;
ts->getattribute ("searchpath", &path);
```

Note: When retrieving a string, you need to pass a pointer to the `char*`, not a pointer to the first character. Also, the `char*` will end up pointing to characters owned by the *ImageCache*; the caller does not need to ever free the memory that contains the characters.

Parameters

- **name** – Name of the attribute to retrieve.
- **type** – *TypeDesc* describing the type of the attribute.
- **val** – Pointer where the attribute value should be stored.

Returns

true if the name and type were recognized and the attribute was retrieved, or false upon failure (including it being an unrecognized attribute or not of the correct type).

inline bool **getattribute**(string_view name, int &val) const

Specialized [attribute\(\)](#) for retrieving a single int value.

inline bool **getattribute**(string_view name, float &val) const

Specialized [attribute\(\)](#) for retrieving a single float value.

inline bool **getattribute**(string_view name, char **val) const

Specialized [attribute\(\)](#) for retrieving a single string value as a char*.

inline bool **getattribute**(string_view name, std::string &val) const

Specialized [attribute\(\)](#) for retrieving a single string value as a std::string.

TypeDesc **getattributetype**(string_view name) const

If the named attribute is known, return its data type. If no such attribute exists, return TypeUnknown.

This was added in version 2.5.

Opaque data for performance lookups

The *TextureSystem* implementation needs to maintain certain per-thread state, and some methods take an opaque *Perthread* pointer to this record. There are three options for how to deal with it:

- Don't worry about it at all: don't use the methods that want *Perthread* pointers, or always pass `nullptr` for any ``Perthread*1` arguments, and *ImageCache* will do thread-specific-pointer retrieval as necessary (though at some small cost).
- If your app already stores per-thread information of its own, you may call `get_perthread_info(nullptr)` to retrieve it for that thread, and then pass it into the functions that allow it (thus sparing them the need and expense of retrieving the thread-specific pointer). However, it is crucial that this pointer not be shared between multiple threads. In this case, the *ImageCache* manages the storage, which will automatically be released when the thread terminates.
- If your app also wants to manage the storage of the *Perthread*, it can explicitly create one with `create_perthread_info()`, pass it around, and eventually be responsible for destroying it with `destroy_perthread_info()`. When managing the storage, the app may reuse the *Perthread* for another thread after the first is terminated, but still may not use the same *Perthread* for two threads running concurrently.

Perthread ***get_perthread_info**(*Perthread* *thread_info = nullptr)

Retrieve a *Perthread*, unique to the calling thread. This is a thread-specific pointer that will always return the *Perthread* for a thread, which will also be automatically destroyed when the thread terminates.

Applications that want to manage their own *Perthread* pointers (with `create_thread_info` and `destroy_thread_info`) should still call this, but passing in their managed pointer. If the passed-in `thread_info` is not `nullptr`, it won't create a new one or retrieve a TSP, but it will do other necessary house-keeping on the *Perthread* information.

Perthread ***create_thread_info**()

Create a new *Perthread*. It is the caller's responsibility to eventually destroy it using [destroy_thread_info\(\)](#).

void **destroy_thread_info**(*Perthread* *threadinfo)

Destroy a *Perthread* that was allocated by [create_thread_info\(\)](#).

TextureHandle ***get_texture_handle**(*ustring* filename, Perthread *thread_info = nullptr, const TextureOpt *options = nullptr)

Retrieve an opaque handle for fast texture lookups. The filename is presumed to be UTF-8 encoded. The options, if not null, may be used to create a separate handle for certain texture option choices (currently: the colorspace). The opaque pointer `thread_info` is thread-specific information returned by `get_perthread_info()`. Return nullptr if something has gone horribly wrong.

inline TextureHandle ***get_texture_handle**(const std::wstring &filename, Perthread *thread_info = nullptr, const TextureOpt *options = nullptr)

Get a TextureHandle using a UTF-16 encoded wstring filename.

bool **good**(TextureHandle *texture_handle)

Return true if the texture handle (previously returned by `get_image_handle()`) is a valid texture that can be subsequently read.

ustring **filename_from_handle**(TextureHandle *handle)

Given a handle, return the UTF-8 encoded filename for that texture.

This method was added in OpenImageIO 2.3.

int **get_colortransform_id**(*ustring* fromspace, *ustring* tospace) const

Retrieve an id for a color transformation by name. This ID can be used as the value for `TextureOpt::colortransformid`. The returned value will be -1 if either color space is unknown, and 0 for a null transformation.

Texture lookups

bool **texture**(*ustring* filename, TextureOpt &options, float s, float t, float dsdx, float dtdx, float dsdy, float dtdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr)

Perform a filtered 2D texture lookup on a position centered at 2D coordinates (*s*, *t*) from the texture identified by `filename`, and using relevant texture options. The `nchannels` parameter determines the number of channels to retrieve (e.g., 1 for a single value, 3 for an RGB triple, etc.). The filtered results will be stored in `result[0..nchannels-1]`.

We assume that this lookup will be part of an image that has pixel coordinates *x* and *y*. By knowing how *s* and *t* change from pixel to pixel in the final image, we can properly *filter* or antialias the texture lookups. This information is given via derivatives *dsdx* and *dtdx* that define the change in *s* and *t* per unit of *x*, and *dsdy* and *dtdy* that define the change in *s* and *t* per unit of *y*. If it is impossible to know the derivatives, you may pass 0 for them, but in that case you will not receive an antialiased texture lookup.

Parameters

- **filename** – The name of the texture, as a UTF-8 encoded *ustring*.
- **options** – Fields within options that are honored for 2D texture lookups include the following:
 - int `firstchannel` : The index of the first channel to look up from the texture.
 - int `subimage` / *ustring* `subimagename` : The subimage or face within the file, specified by either by name (if non-empty) or index. This will be ignored if the file does not have multiple subimages or separate per-face textures.
 - Wrap `swrap`, `twrap` : Specify the *wrap mode* for each direction, one of: `WrapBlack`, `WrapClamp`, `WrapPeriodic`, `WrapMirror`, or `WrapDefault`.
 - float `swidth`, `twidth` : For each direction, gives a multiplier for the derivatives.

- `float sblur, tblur` : For each direction, specifies an additional amount of pre-blur to apply to the texture (*after* derivatives are taken into account), expressed as a portion of the width of the texture.
- `float fill` : Specifies the value that will be used for any color channels that are requested but not found in the file. For example, if you perform a 4-channel lookup on a 3-channel texture, the last channel will get the fill value. (Note: this behavior is affected by the "gray_to_rgb" *TextureSystem* attribute.
- `const float *missingcolor` : If not `nullptr`, specifies the color that will be returned for missing or broken textures (rather than being an error).
- `s/t` – The 2D texture coordinates.
- `dwdx, dwdx, dwdy, dwdy` – The differentials of `s` and `t` relative to canonical directions `x` and `y`. The choice of `x` and `y` are not important to the implementation; it can be any imposed 2D coordinates, such as pixels in screen space, adjacent samples in parameter space on a surface, etc. The `st` derivatives determine the size and shape of the ellipsoid over which the texture lookup is filtered.
- `nchannels` – The number of channels of data to retrieve into `result` (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- `result[]` – The result of the filtered texture lookup will be placed into `result[0..nchannels-1]`.
- `dresultds/dresultdt` – If non-null, these designate storage locations for the derivatives of `result`, i.e., the rate of change per unit `s` and `t`, respectively, of the filtered texture. If supplied, they must allow for `nchannels` of storage.

Returns

`true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

`bool texture(TextureHandle *texture_handle, Perthread *thread_info, TextureOpt &options, float s, float t, float dwdx, float dwdx, float dwdy, float dwdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr)`

Slightly faster version of *texture()* lookup if the app already has a texture handle and per-thread info.

`bool texture3d(usttring filename, TextureOpt &options, V3fParam P, V3fParam dPdx, V3fParam dPdy, V3fParam dPdz, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)`

Perform a filtered 3D volumetric texture lookup on a position centered at 3D position `P` (with given differentials) from the texture identified by `filename`, and using relevant texture options. The filtered results will be stored in `result[0..nchannels-1]`.

The `P` coordinate and `dPdx`, `dPdy`, and `dPdz` derivatives are assumed to be in some kind of common global coordinate system (usually “world” space) and will be automatically transformed into volume local coordinates, if such a transformation is specified in the volume file itself.

Parameters

- `filename` – The name of the texture, as a UTF-8 encoded `usttring`.
- `options` – Fields within `options` that are honored for 3D texture lookups include the following:
 - `int firstchannel` : The index of the first channel to look up from the texture.

- `int subimage / ustring subimagename` : The subimage or field within the volume, specified by either by name (if non-empty) or index. This will be ignored if the file does not have multiple subimages or separate per-face textures.
- `Wrap swrap, twrap, rwrap` : Specify the *wrap mode* for each direction, one of: `WrapBlack`, `WrapClamp`, `WrapPeriodic`, `WrapMirror`, or `WrapDefault`.
- `float swidth, twidth, rwidth` : For each direction, gives a multiplier for the derivatives.
- `float sblur, tblur, rblur` : For each direction, specifies an additional amount of pre-blur to apply to the texture (*after* derivatives are taken into account), expressed as a portion of the width of the texture.
- `float fill` : Specifies the value that will be used for any color channels that are requested but not found in the file. For example, if you perform a 4-channel lookup on a 3-channel texture, the last channel will get the fill value. (Note: this behavior is affected by the "gray_to_rgb" *TextureSystem* attribute.
- `const float *missingcolor` : If not `nullptr`, specifies the color that will be returned for missing or broken textures (rather than being an error).
- `float time` : A time value to use if the volume texture specifies a time-varying local transformation (default: 0).
- **P** – The 2D texture coordinates.
- **dPdx/dPdy/dPdz** – The differentials of P. We assume that this lookup will be part of an image that has pixel coordinates `x` and `y` and depth `z`. By knowing how P changes from pixel to pixel in the final image, and as we step in `z` depth, we can properly *filter* or antialias the texture lookups. This information is given via derivatives `dPdx`, `dPdy`, and `dPdz` that define the changes in P per unit of `x`, `y`, and `z`, respectively. If it is impossible to know the derivatives, you may pass 0 for them, but in that case you will not receive an antialiased texture lookup.
- **nchannels** – The number of channels of data to retrieve into `result` (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- **result[]** – The result of the filtered texture lookup will be placed into `result[0..nchannels-1]`.
- **dresultds/dresultdt/dresultdr** – If non-null, these designate storage locations for the derivatives of result, i.e., the rate of change per unit `s`, `t`, and `r`, respectively, of the filtered texture. If supplied, they must allow for `nchannels` of storage.

Returns

`true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

bool **texture3d**(TextureHandle *texture_handle, Perthread *thread_info, TextureOpt &options, V3fParam P, V3fParam dPdx, V3fParam dPdy, V3fParam dPdz, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)

Slightly faster version of *texture3d()* lookup if the app already has a texture handle and per-thread info.

bool **environment**(ustring filename, TextureOpt &options, V3fParam R, V3fParam dRdx, V3fParam dRdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr)

Perform a filtered directional environment map lookup in the direction of vector `R`, from the texture identified by `filename`, and using relevant texture options. The filtered results will be stored in `result[]`.

Parameters

- **filename** – The name of the texture, as a UTF-8 encode ustring.
- **options** – Fields within **options** that are honored for environment lookups include the following:
 - **int firstchannel** : The index of the first channel to look up from the texture.
 - **int subimage / ustring subimagename** : The subimage or face within the file, specified by either by name (if non-empty) or index. This will be ignored if the file does not have multiple subimages or separate per-face textures.
 - **float swidth, twidth** : For each direction, gives a multiplier for the derivatives.
 - **float sblur, tblur** : For each direction, specifies an additional amount of pre-blur to apply to the texture (*after* derivatives are taken into account), expressed as a portion of the width of the texture.
 - **float fill** : Specifies the value that will be used for any color channels that are requested but not found in the file. For example, if you perform a 4-channel lookup on a 3-channel texture, the last channel will get the fill value. (Note: this behavior is affected by the "gray_to_rgb" *TextureSystem* attribute.
 - **const float *missingcolor** : If not **nullptr**, specifies the color that will be returned for missing or broken textures (rather than being an error).
- **R** – The direction vector to look up.
- **dRdx/dRdy** – The differentials of R with respect to image coordinates x and y.
- **nchannels** – The number of channels of data to retrieve into **result** (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- **result[]** – The result of the filtered texture lookup will be placed into **result[0..nchannels-1]**.
- **dresultds/dresultdt** – If non-null, these designate storage locations for the derivatives of result, i.e., the rate of change per unit s and t, respectively, of the filtered texture. If supplied, they must allow for **nchannels** of storage.

Returns

true upon success, or **false** if the file was not found or could not be opened by any available ImageIO plugin.

bool environment(TextureHandle *texture_handle, Perthread *thread_info, TextureOpt &options, V3fParam R, V3fParam dRdx, V3fParam dRdy, int nchannels, float *result, float *dresultds = **nullptr**, float *dresultdt = **nullptr**)

Slightly faster version of *environment()* if the app already has a texture handle and per-thread info.

Batched texture lookups

bool texture(*ustring* filename, TextureOptBatch &options, Tex::RunMask mask, const float *s, const float *t, const float *dsdx, const float *dtdx, const float *dsdy, const float *dtdy, int nchannels, float *result, float *dresultds = **nullptr**, float *dresultdt = **nullptr**)

Perform filtered 2D texture lookups on a batch of positions from the same texture, all at once. The parameters **s**, **t**, **dsdx**, **dtdx**, and **dsdy**, **dtdy** are each a pointer to [BatchWidth] values. The mask determines which of those array elements to actually compute.

The float* results act like **float[nchannels][BatchWidth]**, so that effectively **result[0..BatchWidth-1]** are the “red” result for each lane, **result[BatchWidth..2*BatchWidth-1]** are the

“green” results, etc. The `dresultds` and `dresultdt` should either both be provided, or else both be `nullptr` (meaning no derivative results are required).

Parameters

- **filename** – The name of the texture, as a UTF-8 encode ustring.
- **options** – A `TextureOptBatch` containing texture lookup options. This is conceptually the same as a `TextureOpt`, but the following fields are arrays of `[BatchWidth]` elements: `sblur`, `tblur`, `swidth`, `twidth`. The other fields are, as with `TextureOpt`, ordinary scalar values.
- **mask** – A bit-field designating which “lanes” should be computed: if `mask & (1<<i>)` is nonzero, then results should be computed and stored for `result[...][i]`.
- **s/t** – Pointers to the 2D texture coordinates, each as a `float[BatchWidth]`.
- **dsdx/dtdx/dsdy/dtdy** – The differentials of `s` and `t` relative to canonical directions `x` and `y`, each as a `float[BatchWidth]`.
- **nchannels** – The number of channels of data to retrieve into `result` (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- **result[]** – The result of the filtered texture lookup will be placed here, as `float[nchannels][BatchWidth]`. (Note the “SOA” data layout.)
- **dresultds/dresultdt** – If non-null, these designate storage locations for the derivatives of `result`, and like `result` are in SOA layout: `float[nchannels][BatchWidth]`

Returns

`true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

```
bool texture(TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options,
             Tex::RunMask mask, const float *s, const float *t, const float *dsdx, const float *dtdx, const
             float *dsdy, const float *dtdy, int nchannels, float *result, float *dresultds = nullptr, float
             *dresultdt = nullptr)
```

Slightly faster version of `texture()` lookup if the app already has a texture handle and per-thread info.

```
bool texture3d(ustring filename, TextureOptBatch &options, Tex::RunMask mask, const float *P, const float
              *dPdx, const float *dPdy, const float *dPdz, int nchannels, float *result, float *dresultds =
              nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)
```

Perform filtered 3D volumetric texture lookups on a batch of positions from the same texture, all at once. The “point-like” parameters `P`, `dPdx`, `dPdy`, and `dPdz` are each a pointers to arrays of `float value[3][BatchWidth]` (or alternately like `Imath::Vec3<FloatWide>`). That is, each one points to all the `x` values for the batch, immediately followed by all the `y` values, followed by the `z` values. The mask determines which of those array elements to actually compute.

The various results arrays are also arranged as arrays that behave as if they were declared `float result[channels][BatchWidth]`, where all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc.

Parameters

- **filename** – The name of the texture, as a UTF-8 encode ustring.
- **options** – A `TextureOptBatch` containing texture lookup options. This is conceptually the same as a `TextureOpt`, but the following fields are arrays of `[BatchWidth]` elements: `sblur`, `tblur`, `swidth`, `twidth`. The other fields are, as with `TextureOpt`, ordinary scalar values.
- **mask** – A bit-field designating which “lanes” should be computed: if `mask & (1<<i>)` is nonzero, then results should be computed and stored for `result[...][i]`.

- **P** – Pointers to the 3D texture coordinates, each as a `float[3][BatchWidth]`.
- **dPdx/dPdy/dPdz** – The differentials of P relative to canonical directions x, y, and z, each as a `float[3][BatchWidth]`.
- **nchannels** – The number of channels of data to retrieve into `result` (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- **result[]** – The result of the filtered texture lookup will be placed here, as `float[nchannels][BatchWidth]`. (Note the “SOA” data layout.)
- **dresultds/dresultdt/dresultdr** – If non-null, these designate storage locations for the derivatives of result, and like `result` are in SOA layout: `float[nchannels][BatchWidth]`

Returns

`true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

```
bool texture3d(TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options,
               Tex::RunMask mask, const float *P, const float *dPdx, const float *dPdy, const float *dPdz,
               int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float
               *dresultdr = nullptr)
```

Slightly faster version of `texture3d()` lookup if the app already has a texture handle and per-thread info.

```
bool environment(ustring filename, TextureOptBatch &options, Tex::RunMask mask, const float *R, const
                 float *dRdx, const float *dRdy, int nchannels, float *result, float *dresultds = nullptr, float
                 *dresultdt = nullptr)
```

Perform filtered directional environment map lookups on a batch of directions from the same texture, all at once. The “point-like” parameters R, dRdx, and dRdy are each a pointers to arrays of `float value[3][BatchWidth]` (or alternately like `Imath::Vec3<FloatWide>`). That is, each one points to all the *x* values for the batch, immediately followed by all the *y* values, followed by the *z* values. The mask determines which of those array elements to actually compute.

The various results arrays are also arranged as arrays that behave as if they were declared `float result[channels][BatchWidth]`, where all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc.

Parameters

- **filename** – The name of the texture, as a UTF-8 encode ustring.
- **options** – A `TextureOptBatch` containing texture lookup options. This is conceptually the same as a `TextureOpt`, but the following fields are arrays of `[BatchWidth]` elements: `sblur`, `tblur`, `swidth`, `twidht`. The other fields are, as with `TextureOpt`, ordinary scalar values.
- **mask** – A bit-field designating which “lanes” should be computed: if `mask & (1<<i>)` is nonzero, then results should be computed and stored for `result[...][i]`.
- **R** – Pointers to the 3D texture coordinates, each as a `float[3][BatchWidth]`.
- **dRdx/dRdy** – The differentials of R relative to canonical directions x and y, each as a `float[3][BatchWidth]`.
- **nchannels** – The number of channels of data to retrieve into `result` (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- **result[]** – The result of the filtered texture lookup will be placed here, as `float[nchannels][BatchWidth]`. (Note the “SOA” data layout.)
- **dresultds/dresultdt** – If non-null, these designate storage locations for the derivatives of result, and like `result` are in SOA layout: `float [nchannels][BatchWidth]`

Returns

`true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

bool **environment**(TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options, Tex::RunMask mask, const float *R, const float *dRdx, const float *dRdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr)

Slightly faster version of *environment()* if the app already has a texture handle and per-thread info.

Texture metadata and raw texels

std::string **resolve_filename**(const std::string &filename) const

Given possibly-relative 'filename' (UTF-8 encoded), resolve it using the search path rules and return the full resolved filename.

bool **get_texture_info**(ustring filename, int subimage, ustring dataname, TypeDesc datatype, void *data)

Get information or metadata about the named texture and store it in *data.

Data names may include any of the following:

- **exists** (int): Stores the value 1 if the file exists and is an image format that OpenImageIO can read, or 0 if the file does not exist, or could not be properly read as a texture. Note that unlike all other queries, this query will “succeed” (return `true`) even if the file does not exist.
- **udim** (int): Stores the value 1 if the file is a “virtual UDIM” or texture atlas file (as described in Section [:ref:sec-texturesys-udim](#)) or 0 otherwise.
- **subimages** (int): The number of subimages/faces in the file, as an integer.
- **resolution** (int[2] or int[3]): The resolution of the texture file, if an array of 2 integers (described as `TypeDesc(INT, 2)`), or the 3D resolution of the texture file, which is an array of 3 integers (described as `TypeDesc(INT, 3)`) The third value will be 1 unless it's a volumetric (3D) image.
- **miplevels** (int): The number of MIPmap levels for the specified subimage (an integer).
- **texturetype** (string): A string describing the type of texture of the given file, which describes how the texture may be used (also which texture API call is probably the right one for it). This currently may return one of: “unknown”, “Plain Texture”, “Volume Texture”, “Shadow”, or “Environment”.
- **textureformat** (string): A string describing the format of the given file, which describes the kind of texture stored in the file. This currently may return one of: “unknown”, “Plain Texture”, “Volume Texture”, “Shadow”, “CubeFace Shadow”, “Volume Shadow”, “LatLong Environment”, or “CubeFace Environment”. Note that there are several kinds of shadows and environment maps, all accessible through the same API calls.
- **channels** (int): The number of color channels in the file.
- **format** (int): The native data format of the pixels in the file (an integer, giving the `TypeDesc::BASETYPE` of the data). Note that this is not necessarily the same as the data format stored in the image cache.
- **cachedformat** (int): The native data format of the pixels as stored in the image cache (an integer, giving the `TypeDesc::BASETYPE` of the data). Note that this is not necessarily the same as the native data format of the file.
- **datawindow** (int[4] or int[6]): Returns the pixel data window of the image, which is either an array of 4 integers (returning xmin, ymin, xmax, ymax) or an array of 6 integers (returning xmin, ymin, zmin,

xmax, ymax, zmax). The z values may be useful for 3D/volumetric images; for 2D images they will be 0).

- **displaywindow** (matrix) : Returns the display (a.k.a. full) window of the image, which is either an array of 4 integers (returning xmin, ymin, xmax, ymax) or an array of 6 integers (returning xmin, ymin, zmin, xmax, ymax, zmax). The z values may be useful for 3D/volumetric images; for 2D images they will be 0).
- **worldtocamera** (matrix) : The viewing matrix, which is a 4x4 matrix (an `Imath::M44f`, described as `TypeMatrix44`) giving the world-to-camera 3D transformation matrix that was used when the image was created. Generally, only rendered images will have this.
- **worldtoscreen** (matrix) : The projection matrix, which is a 4x4 matrix (an `Imath::M44f`, described as `TypeMatrix44`) giving the matrix that projected points from world space into a 2D screen coordinate system where *x* and *y* range from -1 to +1. Generally, only rendered images will have this.
- **worldtoNDC** (matrix) : The projection matrix, which is a 4x4 matrix (an `Imath::M44f`, described as `TypeMatrix44`) giving the matrix that projected points from world space into a 2D screen coordinate system where *x* and *y* range from 0 to +1. Generally, only rendered images will have this.
- **averagecolor** (float[nchannels]) : If available in the metadata (generally only for files that have been processed by `maketx`), this will return the average color of the texture (into an array of floats).
- **averagealpha** (float) : If available in the metadata (generally only for files that have been processed by `maketx`), this will return the average alpha value of the texture (into a float).
- **constantcolor** (float[nchannels]) : If the metadata (generally only for files that have been processed by `maketx`) indicates that the texture has the same values for all pixels in the texture, this will retrieve the constant color of the texture (into an array of floats). A non-constant image (or one that does not have the special metadata tag identifying it as a constant texture) will fail this query (return false).
- **constantalpha** (float) : If the metadata indicates that the texture has the same values for all pixels in the texture, this will retrieve the constant alpha value of the texture. A non-constant image (or one that does not have the special metadata tag identifying it as a constant texture) will fail this query (return false).
- **stat:tilesread** (int64) : Number of tiles read from this file.
- **stat:bytesread** (int64) : Number of bytes of uncompressed pixel data read
- **stat:redundant_tiles** (int64) : Number of times a tile was read, where the same tile had been read before.
- **stat:redundant_bytesread** (int64) : Number of bytes (of uncompressed pixel data) in tiles that were read redundantly.
- **stat:redundant_bytesread** (int) : Number of tiles read from this file.
- **stat:timesopened** (int) : Number of times this file was opened.
- **stat:iotime** (float) : Time (in seconds) spent on all I/O for this file.
- **stat:mipsused** (int) : Stores 1 if any MIP levels beyond the highest resolution were accessed, otherwise 0.
- **stat:is_duplicate** (int) : Stores 1 if this file was a duplicate of another image, otherwise 0.
- *Anything else* : For all other data names, the the metadata of the image file will be searched for an item that matches both the name and data type.

Parameters

- **filename** – The name of the texture, as a UTF-8 encode ustring.

- **subimage** – The subimage to query. (The metadata retrieved is for the highest-resolution MIP level of that subimage.)
- **dataname** – The name of the metadata to retrieve.
- **datatype** – *TypeDesc* describing the data type.
- **data** – Pointer to the caller-owned memory where the values should be stored. It is the caller's responsibility to ensure that data points to a large enough storage area to accommodate the datatype requested.

Returns

true if `get_textureinfo()` is able to find the requested `dataname` for the texture and it matched the requested `datatype`. If the requested data was not found or was not of the right data type, return false. Except for the "exists" query, a file that does not exist or could not be read properly as an image also constitutes a query failure that will return false.

bool **get_texture_info**(TextureHandle *texture_handle, Perthread *thread_info, int subimage, *ustring* dataname, *TypeDesc* datatype, void *data)

A more efficient variety of `get_textureinfo()` for cases where you can use a `TextureHandle*` to specify the image and optionally have a `Perthread*` for the calling thread.

bool **get_imagespec**(*ustring* filename, *ImageSpec* &spec, int subimage = 0)

Copy the *ImageSpec* associated with the named texture (the first subimage by default, or as set by subimage).

Parameters

- **filename** – The name of the texture, as a UTF-8 encode *ustring*.
- **subimage** – The subimage to query. (The spec retrieved is for the highest-resolution MIP level of that subimage.)
- **spec** – *ImageSpec* into which will be copied the spec for the requested image.

Returns

true upon success, false upon failure failure (such as being unable to find, open, or read the file, or if it does not contain the designated subimage or MIP level).

bool **get_imagespec**(TextureHandle *texture_handle, Perthread *thread_info, *ImageSpec* &spec, int subimage = 0)

A more efficient variety of `get_imagespec()` for cases where you can use a `TextureHandle*` to specify the image and optionally have a `Perthread*` for the calling thread.

inline bool **get_imagespec**(*ustring* filename, int subimage, *ImageSpec* &spec)

DEPRECATED old API. Note that the spec and subimage parameters are inverted. We recommend switching to the new API.

const *ImageSpec* ***imagespec**(*ustring* filename, int subimage = 0)

Return a pointer to an *ImageSpec* associated with the named texture if the file is found and is an image format that can be read, otherwise return `nullptr`.

This method is much more efficient than `get_imagespec()`, since it just returns a pointer to the spec held internally by the *TextureSystem* (rather than copying the spec to the user's memory). However, the caller must beware that the pointer is only valid as long as nobody (even other threads) calls `invalidate()` on the file, or `invalidate_all()`, or destroys the *TextureSystem* and its underlying *ImageCache*.

Parameters

- **filename** – The name of the texture, as a UTF-8 encode *ustring*.

- **subimage** – The subimage to query. (The spec retrieved is for the highest-resolution MIP level of that subimage.)

Returns

A pointer to the spec, if the image is found and able to be opened and read by an available image format plugin, and the designated subimage exists.

```
const ImageSpec *imagespec(TextureHandle *texture_handle, Perthread *thread_info = nullptr, int subimage = 0)
```

A more efficient variety of *imagespec()* for cases where you can use a *TextureHandle** to specify the image and optionally have a *Perthread** for the calling thread.

```
bool get_texels(ustring filename, TextureOpt &options, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, TypeDesc format, void *result)
```

For a texture specified by name, retrieve the rectangle of raw unfiltered texels from the subimage specified in *options* and at the designated *miplevel*, storing the pixel values beginning at the address specified by *result*. The pixel values will be converted to the data type specified by *format*. The rectangular region to be retrieved includes *begin* but does not include *end* (much like STL *begin/end* usage). Requested pixels that are not part of the valid pixel data region of the image file will be filled with zero values. Channels requested but not present in the file will get the *options.fill* value.

Parameters

- **filename** – The name of the texture, as a UTF-8 encode *ustring*.
- **options** – A *TextureOpt* describing access options, including wrap modes, fill value, and subimage, that will be used when retrieving pixels.
- **miplevel** – The MIP level to retrieve pixels from (0 is the highest resolution level).
- **xbegin/xend/ybegin/yend/zbegin/zend** – The range of pixels to retrieve. The pixels retrieved include the *begin* value but not the *end* value (much like STL *begin/end* usage).
- **chbegin/chend** – Channel range to retrieve. To retrieve all channels, use *chbegin* = 0, *chend* = *nchannels*.
- **format** – *TypeDesc* describing the data type of the values you want to retrieve into *result*. The pixel values will be converted to this type regardless of how they were stored in the file or in the cache.
- **result** – Pointer to the memory where the pixel values should be stored. It is up to the caller to ensure that *result* points to an area of memory big enough to accommodate the requested rectangle (taking into consideration its dimensions, number of channels, and data format).

Returns

true for success, *false* for failure.

```
bool get_texels(TextureHandle *texture_handle, Perthread *thread_info, TextureOpt &options, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, TypeDesc format, void *result)
```

A more efficient variety of *get_texels()* for cases where you can use a *TextureHandle** to specify the image and optionally have a *Perthread** for the calling thread.

Methods for UDIM patterns

bool **is_udim**(*ustring* filename)

Is the UTF-8 encoded filename a UDIM pattern?

This method was added in OpenImageIO 2.3.

bool **is_udim**(TextureHandle *udimfile)

Does the handle refer to a file that's a UDIM pattern?

This method was added in OpenImageIO 2.3.

TextureHandle ***resolve_udim**(*ustring* udimpattern, float s, float t)

For a UDIM filename pattern (UTF-8 encoded) and texture coordinates, return the TextureHandle pointer for the concrete tile file it refers to, or nullptr if there is no corresponding tile (udim sets are allowed to be sparse).

This method was added in OpenImageIO 2.3.

TextureHandle ***resolve_udim**(TextureHandle *udimfile, Perthread *thread_info, float s, float t)

A more efficient variety of *resolve_udim()* for cases where you have the TextureHandle* that corresponds to the “virtual” UDIM file and optionally have a Perthread* for the calling thread.

This method was added in OpenImageIO 2.3.

void **inventory_udim**(*ustring* udimpattern, std::vector<*ustring*> &filenames, int &nutiles, int &nvtiles)

Produce a full inventory of the set of concrete files comprising the UDIM set specified by UTF-8 encoded udimpattern. The apparent number of texture atlas tiles in the u and v directions will be written to nutiles and nvtiles, respectively. The vector filenames will be sized to nutiles * nvtiles and filled with the names of the concrete files comprising the atlas, with an empty ustring corresponding to any unpopulated tiles (the UDIM set is allowed to be sparse). The filename list is indexed as utile + vtile * nvtiles.

This method was added in OpenImageIO 2.3.

void **inventory_udim**(TextureHandle *udimfile, Perthread *thread_info, std::vector<*ustring*> &filenames, int &nutiles, int &nvtiles)

A more efficient variety of *inventory_udim()* for cases where you have the TextureHandle* that corresponds to the “virtual” UDIM file and optionally have a Perthread* for the calling thread.

This method was added in OpenImageIO 2.3.

Controlling the cache

void **invalidate**(*ustring* filename, bool force = true)

Invalidate any cached information about the named file (UTF-8 encoded), including loaded texture tiles from that texture, and close any open file handle associated with the file. This calls ImageCache::invalidate(filename, force) on the underlying ImageCache.

void **invalidate_all**(bool force = false)

Invalidate all cached data for all textures. This calls ImageCache::invalidate_all(force) on the underlying ImageCache.

void **close**(*ustring* filename)

Close any open file handles associated with a UTF-8 encoded filename, but do not invalidate any image spec information or pixels associated with the files. A client might do this in order to release OS file handle resources, or to make it safe for other processes to modify textures on disk. This calls ImageCache::close(force) on the underlying ImageCache.

void **close_all()**

close() all files known to the cache.

Errors and statistics

bool **has_error()** const

Is there a pending error message waiting to be retrieved?

std::string **geterror**(bool clear = true) const

Return the text of all pending error messages issued against this *TextureSystem*, and clear the pending error message unless *clear* is false. If no error message is pending, it will return an empty string.

std::string **getstats**(int level = 1, bool icstats = true) const

Returns a big string containing useful statistics about the *TextureSystem* operations, suitable for saving to a file or outputting to the terminal. The *level* indicates the amount of detail in the statistics, with higher numbers (up to a maximum of 5) yielding more and more esoteric information. If *icstats* is true, the returned string will also contain all the statistics of the underlying *ImageCache*, but if false will only contain texture-specific statistics.

void **reset_stats()**

Reset most statistics to be as they were with a fresh *TextureSystem*. Caveat emptor: this does not flush the cache itself, so the resulting statistics from the next set of texture requests will not match the number of tile reads, etc., that would have resulted from a new *TextureSystem*.

Public Functions

std::shared_ptr<*ImageCache*> **imagecache()** const

Return an opaque, non-owning pointer to the underlying *ImageCache* (if there is one).

8.4 UDIM texture atlases

8.4.1 Texture lookups

The *texture()* call supports virtual filenames that expand per lookup for UDIM tiled texture atlases. The substitutions will occur if the texture filename initially passed to *texture()* does not exist as a concrete file and contains one or more of the following substrings:

Pattern	Numbering scheme	Example expansion if u=0.5, v=2.5
<UDIM>	1001 + utile + vtile*10	1021
<u>	utile	u0
<v>	vtile	v2
<U>	utile + 1	u1
<V>	vtile + 1	v3
<uvtile>	equivalent to <u>_<v>	u0_v2
<UVTILE>	equivalent to <U>_<V>	u1_v3
_u##v##	utile, vtile	_u00v02
%(UDIM)d	synonym for <UDIM>	1021

where the tile numbers are derived from the input u,v texture coordinates as follows:

```
// Each unit square of texture is a different tile
utile = max (0, int(u));
vtile = max (0, int(v));
// Re-adjust the texture coordinates to the offsets within the tile
u = u - utile;
v = v - vtile;
```

Example:

```
ustring filename ("paint.<UDIM>.tif");
float s = 1.4, t = 3.8;
texsys->texture (filename, s, t, ...);
```

will retrieve from file `paint.1032.tif` at coordinates (0.4,0.8).

8.4.2 Handles of udim files

Calls to `get_texture_handle()`, when passing a UDIM pattern filename, will always succeed. But without knowing a specific `u` and `v`, it has no way to know that the concrete file you will eventually ask for would not succeed, so this handle is for the overall “virtual” texture atlas.

You can retrieve the handle of a specific “tile” of the UDIM set by using

```
TextureHandle *resolve_udim(ustring udimpattern, float s, float t)
```

```
TextureHandle *resolve_udim(TextureHandle *udimfile, Perthread *thread_info, float s, float t)
```

Note: these will return `nullptr` if the UDIM tile for those coordinates is unpopulated.

Note also that the `is_udim()` method can be used to ask whether a filename or handle corresponds to a UDIM pattern (the whole set of atlas tiles):

```
bool is_udim(ustring filename)
```

```
bool is_udim(TextureHandle *udimfile)
```

8.4.3 Retrieving metadata from UDIM sets and tiles

Calls to `get_texture_info()` on UDIM file pattern will succeed if the metadata is found and has the same value in all of the populated “tiles” of a UDIM. If not all populated tile files have the same value for that attribute, the call will fail.

If you want to know the metadata at a specific texture coordinate, you can use a combination of `resolve_udim()` to find the handle for the corresponding concrete texture file for that “tile,” and then `get_texture_info()` to retrieve the metadata for the concrete file.

8.4.4 Full inventory of a UDIM set

You can get the range in `u` and `v` of the UDIM texture atlas, and the list of all of the concrete filenames of the corresponding tiles with this method:

```
void inventory_udim(ustring udimpattern, std::vector<ustring> &filenames, int &nutils, int &nvtiles)
```

```
void inventory_udim(TextureHandle *udimfile, Perthread *thread_info, std::vector<ustring> &filenames, int
&nutils, int &nvtiles)
```

The indexing scheme is that `filenames[u + v * nvtiles]` is the name of the tile with integer indices (u, v) , where 0 is the first index of each row or column.

The combination of `inventory_udim()` and `get_texture_handle()` of the listed filenames can be used to generate the corresponding handles for each UDIM tile.

8.5 Batched Texture Lookups

On CPU architectures with SIMD processing, texturing entire batches of samples at once may provide a large speedup compared to texturing each sample point individually. The batch size is fixed (for any build of OpenImageIO) and may be accessed with the following constant:

```
constexpr int OIIO::Tex::BatchWidth = OIIO_TEXTURE_SIMD_BATCH_WIDTH
```

The SIMD width for batched texturing operations. This is fixed within any release of OpenImageIO, but may change from release to release and also may be overridden at build time. A typical batch size is 16.

```
typedef simd::VecType<float, OIIO_TEXTURE_SIMD_BATCH_WIDTH>::type OIIO::Tex::FloatWide
```

A type alias for a SIMD vector of floats with the batch width.

```
typedef simd::VecType<int, OIIO_TEXTURE_SIMD_BATCH_WIDTH>::type OIIO::Tex::IntWide
```

A type alias for a SIMD vector of ints with the batch width.

All of the batched calls take a *run mask*, which describes which subset of “lanes” should be computed by the batched lookup:

```
typedef uint64_t OIIO::Tex::RunMask
```

RunMask is defined to be an integer large enough to hold at least **BatchWidth** bits. The least significant bit corresponds to the first (i.e., [0]) position of all batch arrays. For each position *i* in the batch, the bit identified by $(1 \ll i)$ controls whether that position will be computed.

enumerator **RunMaskOn**

The defined constant **RunMaskOn** contains the value with all bits $0 \dots \text{BatchWidth}-1$ set to 1.

8.5.1 Batched Options

TextureOptBatch is a structure that holds the options for doing an entire batch of lookups from the same texture at once. The members of **TextureOptBatch** correspond to the similarly named members of the single-point **TextureOpt**, so we refer you to Section [TextureOpt](#) for detailed explanations, and this section will only explain the differences between batched and single-point options. Members include:

- `int firstchannel:`
- `int subimage, ustring subimagename:`
- `Wrap swrap, twrap, rwrap:`
- `float fill:`
- `const float* missingcolor:`
- `MipMode mipmode:`
- `InterpMode interpmode:`
- `int anisotropic:`

- `bool conservative_filter :`

These fields are all scalars — a single value for each `TextureOptBatch` — which means that the value of these options must be the same for every texture sample point within a batch. If you have a number of texture lookups to perform for the same texture, but they have (for example) differing wrap modes or subimages from point to point, then you must split them into separate batch calls.

- `float sblur[Tex::BatchWidth] :`
- `float tblur[Tex::BatchWidth] :`
- `float rblur[Tex::BatchWidth] :`

These arrays hold the `s`, and `t` blur amounts, for each sample in the batch, respectively. (And the `r` blur amount, used only for volumetric `texture3d()` lookups.)

- `float swidth[Tex::BatchWidth] :`
- `float twidth[Tex::BatchWidth] :`
- `float rwidth[Tex::BatchWidth] :`

These arrays hold the `s`, and `t` filtering width multiplier for derivatives, for each sample in the batch, respectively. (And the `r` multiplier, used only for volumetric `texture3d()` lookups.)

8.5.2 Batched Texture Lookup Calls

```
bool TextureSystem::texture(ustring filename, TextureOptBatch &options, Tex::RunMask mask, const float *s,
                           const float *t, const float *dsdx, const float *dtdx, const float *dsdy, const float
                           *dtdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt =
                           nullptr)
```

```
bool TextureSystem::texture(TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch
                           &options, Tex::RunMask mask, const float *s, const float *t, const float *dsdx,
                           const float *dtdx, const float *dsdy, const float *dtdy, int nchannels, float *result,
                           float *dresultds = nullptr, float *dresultdt = nullptr)
```

Perform filtered 2D texture lookups on a batch of positions from the same texture, all at once. The parameters `s`, `t`, `dsdx`, `dtdx`, and `dsdy`, `dtdy` are each a pointer to `[BatchWidth]` values. The mask determines which of those array elements to actually compute.

The various results are arranged as arrays that behave as if they were declared:

<code>float result[channels][BatchWidth]</code>

In other words, all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc. (This is “SOA” order.)

This function returns `true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

```
bool texture3d(ustring filename, TextureOptBatch &options, Tex::RunMask mask, const float *P, const float
               *dPdx, const float *dPdy, const float *dPdz, int nchannels, float *result, float *dresultds = nullptr,
               float *dresultdt = nullptr, float *dresultdr = nullptr)
```

```
bool texture3d(TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options, Tex::RunMask
               mask, const float *P, const float *dPdx, const float *dPdy, const float *dPdz, int nchannels, float
               *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)
```

Perform filtered 3D volumetric texture lookups on a batch of positions from the same texture, all at once. The “point-like” parameters `P`, `dPdx`, `dPdy`, and `dPdz` are each a pointers to arrays of `float`

`value[3][BatchWidth]`. That is, each one points to all the *x* values for the batch, immediately followed by all the *y* values, followed by the *z* values.

The various results arrays are also arranged as arrays that behave as if they were declared `float result[channels][BatchWidth]`, where all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc.

This function returns `true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

```
bool environment(ustring filename, TextureOptBatch &options, Tex::RunMask mask, const float *R, const float
                  *dRdx, const float *dRdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt
                  = nullptr)
```

```
bool environment(TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options,
                  Tex::RunMask mask, const float *R, const float *dRdx, const float *dRdy, int nchannels, float
                  *result, float *dresultds = nullptr, float *dresultdt = nullptr)
```

Perform filtered directional environment map lookups on a batch of positions from the same texture, all at once. The “point-like” parameters *R*, *dRdx*, and *dRdy* are each a pointers to arrays of `float value[3][BatchWidth]`. That is, each one points to all the *x* values for the batch, immediately followed by all the *y* values, followed by the *z* values.

Perform filtered directional environment map lookups on a collection of directions all at once, which may be much more efficient than repeatedly calling the single-point version of `environment()`. The parameters *R*, *dRdx*, and *dRdy* are now `VaryingRef`’s that may refer to either a single or an array of values, as are many the fields in the `options`.

The various results arrays are also arranged as arrays that behave as if they were declared `float result[channels][BatchWidth]`, where all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc.

This function returns `true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

IMAGEBUF: IMAGE BUFFERS

9.1 ImageBuf Introduction and Theory of Operation

ImageBuf is a utility class that stores an entire image. It provides a nice API for reading, writing, and manipulating images as a single unit, without needing to worry about any of the details of storage or I/O.

All I/O involving ImageBuf (that is, calls to `read` or `write`) are implemented underneath in terms of ImageCache, ImageInput, and ImageOutput, and so support all of the image file formats supported by OIIO.

The ImageBuf class definition requires that you:

```
#include <OpenImageIO/imagebuf.h>
```

enum OIIO::ImageBuf::IBStorage

An ImageBuf can store its pixels in one of several ways (each identified by an IBStorage enumerated value):

Values:

enumerator **UNINITIALIZED**

An ImageBuf that doesn't represent any image at all (either because it is newly constructed with the default constructor, or had an error during construction).

enumerator **LOCALBUFFER**

"Local storage" is allocated to hold the image pixels internal to the ImageBuf. This memory will be freed when the ImageBuf is destroyed.

enumerator **APPBUFFER**

The ImageBuf "wraps" pixel memory already allocated and owned by the calling application. The caller will continue to own that memory and be responsible for freeing it after the ImageBuf is destroyed.

enumerator **IMAGECACHE**

The ImageBuf is "backed" by an *ImageCache*, which will automatically be used to retrieve pixels when requested, but the ImageBuf will not allocate separate storage for it. This brings all the advantages of the *ImageCache*, but can only be used for read-only ImageBuf's that reference a stored image file.

9.2 Constructing, destructing, resetting an ImageBuf

There are several ways to construct an ImageBuf. Each constructor has a corresponding `reset` method that takes the same arguments. Calling `reset` on an existing ImageBuf is equivalent to constructing a new ImageBuf from scratch (even if the ImageBuf, prior to reset, previously held an image).

9.2.1 Making an empty or uninitialized ImageBuf

`OIIO::ImageBuf::ImageBuf()`

Default constructor makes an empty/uninitialized ImageBuf. There isn't much you can do with an uninitialized buffer until you call `reset()`. The storage type of a default-constructed ImageBuf is `IBStorage::UNINITIALIZED`.

`inline void OIIO::ImageBuf::reset()`

Destroy any previous contents of the ImageBuf and re-initialize it to resemble a freshly constructed ImageBuf using the default constructor (holding no image, with storage `IBStorage::UNINITIALIZED`).

9.2.2 Constructing a readable ImageBuf

`explicit OIIO::ImageBuf::ImageBuf(string_view name, int subimage = 0, int miplevel = 0,
std::shared_ptr<ImageCache> imagecache = {}, const ImageSpec *config =
nullptr, Filesystem::IOProxy *ioproxy = nullptr)`

Construct a read-only ImageBuf that will be used to read the named file (at the given subimage and MIP-level, defaulting to the first in the file). But don't read it yet! The image will actually be read lazily, only when other methods need to access the spec and/or pixels, or when an explicit call to `init_spec()` or `read()` is made, whichever comes first.

The implementation may end up either reading the entire image internally owned memory (if so, the storage will be `LOCALBUFFER`), or it may rely on being backed by an *ImageCache* (in this case, the storage will be `IMAGECACHE`) depending on the image size and other factors.

Parameters

- **name** – The image to read.
- **subimage/miplevel** – The subimage and MIP level to read (defaults to the first subimage of the file, highest-res MIP level).
- **imagecache** – Optionally, an *ImageCache* to use, if possible, rather than reading the entire image file into memory.
- **config** – Optionally, a pointer to an *ImageSpec* whose metadata contains configuration hints that set options related to the opening and reading of the file.
- **ioproxy** – Optional pointer to an IOProxy to use when reading from the file. The caller retains ownership of the proxy, and must ensure that it remains valid for the lifetime of the ImageBuf.

`void OIIO::ImageBuf::reset(string_view name, int subimage = 0, int miplevel = 0,
std::shared_ptr<ImageCache> imagecache = {}, const ImageSpec *config = nullptr,
Filesystem::IOProxy *ioproxy = nullptr)`

Destroy any previous contents of the ImageBuf and re-initialize it as if newly constructed with the same arguments, as a read-only representation of an existing image file.

9.2.3 Constructing a writable ImageBuf

explicit OIII0: :ImageBuf: :**ImageBuf**(const *ImageSpec* &spec, InitializePixels zero = InitializePixels::Yes)

Construct a writable ImageBuf with the given specification (including resolution, data type, metadata, etc.). The ImageBuf will allocate and own its own pixel memory and will free that memory automatically upon destruction, `clear()`, or `reset()`. Upon successful initialization, the storage will be reported as LOCALBUFFER.

Parameters

- **spec** – An *ImageSpec* describing the image and its metadata. If not enough information is given to know how much memory to allocate (width, height, depth, channels, and data format), the ImageBuf will remain in an UNINITIALIZED state and will have no local pixel storage.
- **zero** – After a successful allocation of the local pixel storage, this parameter controls whether the pixels will be initialized to hold zero (black) values (`InitializePixels::Yes`) or if the pixel memory will remain uninitialized (`InitializePixels::No`) and thus may hold nonsensical values. Choosing No may save the time of writing to the pixel memory if you know for sure that you are about to overwrite it completely before you will need to read any pixel values.

void OIII0: :ImageBuf: :**reset**(const *ImageSpec* &spec, InitializePixels zero = InitializePixels::Yes)

Destroy any previous contents of the ImageBuf and re-initialize it as if newly constructed with the same arguments, as a read/write image with locally allocated storage that can hold an image as described by *spec*. The optional *zero* parameter controls whether the pixel values are filled with black/empty, or are left uninitialized after being allocated.

Note that if the *ImageSpec* does not contain enough information to specify how much memory to allocate (width, height, channels, and data format), the ImageBuf will remain uninitialized (regardless of how *zero* is set).

bool OIII0: :ImageBuf: :**make_writable**(bool keep_cache_type = false)

Make the ImageBuf be writable. That means that if it was previously backed by an *ImageCache* (storage was IMAGECACHE), it will force a full read so that the whole image is in local memory. This will invalidate any current iterators on the image. It has no effect if the image storage is not IMAGECACHE.

Parameters

keep_cache_type – If true, preserve any ImageCache-forced data types (you might want to do this if it is critical that the apparent data type doesn't change, for example if you are calling `make_writable()` from within a type-specialized function).

Returns

Return `true` if it works (including if no read was necessary), `false` if something went horribly wrong.

9.2.4 Constructing an ImageBuf that “wraps” an application buffer

OIII0: :ImageBuf: :**ImageBuf**(const *ImageSpec* &spec, void *buffer, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

void OIII0: :ImageBuf: :**reset**(const *ImageSpec* &spec, void *buffer, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

Unsafe reset of a “wrapped” buffer, mostly for backward compatibility. This version does not pass a span that explicitly delineates the memory bounds, but only passes a raw pointer and assumes that the caller has ensured that the buffer pointed to is big enough to accommodate accessing any valid pixel as describes by the *spec* and the strides. Use with caution!

9.2.5 Reading and Writing disk images

```
bool OIIO::ImageBuf::read(int subimage = 0, int miplevel = 0, bool force = false, TypeDesc convert =
    TypeUnknown, ProgressCallback progress_callback = nullptr, void
    *progress_callback_data = nullptr)
```

Read the particular subimage and MIP level of the image. Generally, this will skip the expensive read if the file has already been read into the ImageBuf (at the specified subimage and MIP level). It will clear and re-allocate memory if the previously allocated space was not appropriate for the size or data type of the image being read.

In general, `read()` will try not to do any I/O at the time of the `read()` call, but rather to have the ImageBuf “backed” by an *ImageCache*, which will do the file I/O on demand, as pixel values are needed, and in that case the ImageBuf doesn’t actually allocate memory for the pixels (the data lives in the *ImageCache*). However, there are several conditions for which the *ImageCache* will be bypassed, the ImageBuf will allocate “local” memory, and the disk file will be read directly into allocated buffer at the time of the `read()` call: (a) if the `force` parameter is `true`; (b) if the `convert` parameter requests a data format conversion to a type that is not the native file type and also is not one of the internal types supported by the *ImageCache* (specifically, `float` and `uint8`); (c) if the ImageBuf already has local pixel memory allocated, or “wraps” an application buffer.

Note that `read()` is not strictly necessary. If you are happy with the filename, subimage and MIP level specified by the ImageBuf constructor (or the last call to `reset()`), and you want the storage to be backed by the *ImageCache* (including storing the pixels in whatever data format that implies), then the file contents will be automatically read the first time you make any other ImageBuf API call that requires the spec or pixel values. The only reason to call `read()` yourself is if you are changing the filename, subimage, or MIP level, or if you want to use `force=true` or a specific `convert` value to force data format conversion.

Parameters

- **subimage/miplevel** – The subimage and MIP level to read.
- **force** – If `true`, will force an immediate full read into ImageBuf-owned local pixel memory (yielding a LOCALPIXELS storage buffer). Otherwise, it is up to the implementation whether to immediately read or have the image backed by an *ImageCache* (storage IMAGECACHE, if the ImageBuf was originally constructed or reset with an *ImageCache* specified).
- **convert** – If set to a specific type (not UNKNOWN), the ImageBuf memory will be allocated for that type specifically and converted upon read.
- **progress_callback/progress_callback_data** – If `progress_callback` is non-NULL, the underlying read, if expensive, may make several calls to `progress_callback(progress_callback_data, portion_done)` which allows you to implement some sort of progress meter. Note that if the ImageBuf is backed by an *ImageCache*, the progress callback will never be called, since no actual file I/O will occur at this time (*ImageCache* will load tiles or scanlines on demand, as individual pixel values are needed).

Returns

`true` upon success, or `false` if the read failed (in which case, you should be able to retrieve an error message via `geterror()`).

```
bool OIIO::ImageBuf::read(int subimage, int miplevel, int chbegin, int chend, bool force, TypeDesc convert,
    ProgressCallback progress_callback = nullptr, void *progress_callback_data =
    nullptr)
```

Read the file, if possible only allocating and reading a subset of channels, `[chbegin..chend-1]`. This can be a performance and memory improvement for some image file formats, if you know that any use of the ImageBuf will only access a subset of channels from a many-channel file.

Additional parameters:

Parameters

chbegin/chend – The subset (a range with “exclusive end”) of channels to read, if the implementation is able to read only a subset of channels and have a performance advantage by doing so. If **chbegin** is 0 and **chend** is either negative or greater than the number of channels in the file, all channels will be read. Please note that it is “advisory” and not guaranteed to be honored by the underlying implementation.

bool OIIO::ImageBuf::init_spec(string_view filename, int subimage, int miplevel)

Read the *ImageSpec* for the given file, subimage, and MIP level into the ImageBuf, but will not read the pixels or allocate any local storage (until a subsequent call to *read()*). This is helpful if you have an ImageBuf and you need to know information about the image, but don’t want to do a full read yet, and maybe won’t need to do the full read, depending on what’s found in the spec.

Note that *init_spec()* is not strictly necessary. If you are happy with the filename, subimage and MIP level specified by the ImageBuf constructor (or the last call to *reset()*), then the spec will be automatically read the first time you make any other ImageBuf API call that requires it. The only reason to call *read()* yourself is if you are changing the filename, subimage, or MIP level, or if you want to use *force=true* or a specific *convert* value to force data format conversion.

Parameters

- **filename** – The filename to read from (should be the same as the filename used when the ImageBuf was constructed or reset.)
- **subimage/miplevel** – The subimage and MIP level to read.

Returns

true upon success, or false if the read failed (in which case, you should be able to retrieve an error message via *geterror()*).

bool OIIO::ImageBuf::write(string_view filename, TypeDesc dtype = TypeUnknown, string_view fileformat = string_view(), ProgressCallback progress_callback = nullptr, void *progress_callback_data = nullptr) const

Write the image to the named file, converted to the specified pixel data type *dtype* (TypeUnknown signifies to use the data type of the buffer), and file format (an empty *fileformat* means to infer the type from the filename extension).

By default, it will always try to write a scanline-oriented file, unless the *set_write_tiles()* method has been used to override this.

Parameters

- **filename** – The filename to write to.
- **dtype** – Optional override of the pixel data format to use in the file being written. The default (UNKNOWN) means to try writing the same data format that as pixels are stored within the ImageBuf memory (or whatever type was specified by a prior call to *set_write_format()*). In either case, if the file format does not support that data type, another will be automatically chosen that is supported by the file type and loses as little precision as possible.
- **fileformat** – Optional override of the file format to write. The default (empty string) means to infer the file format from the extension of the *filename* (for example, “foo.tif” will write a TIFF file).
- **progress_callback/progress_callback_data** – If *progress_callback* is non-NULL, the underlying write, if expensive, may make several calls to *progress_callback(progress_callback_data, portion_done)* which allows you to implement some sort of progress meter.

Returns

true upon success, or false if the write failed (in which case, you should be able to retrieve an error message via [geterror\(\)](#)).

```
bool OIIO::ImageBuf::write(ImageOutput *out, ProgressCallback progress_callback = nullptr, void
                           *progress_callback_data = nullptr) const
```

Write the pixels of the ImageBuf to an open [ImageOutput](#). The [ImageOutput](#) must have already been opened with a spec that indicates a resolution identical to that of this ImageBuf (but it may have specified a different pixel data type, in which case data conversions will happen automatically). This method does NOT close the file when it's done (and so may be called in a loop to write a multi-image file).

Note that since this uses an already-opened [ImageOutput](#), which is too late to change how it was opened, it does not honor any prior calls to [set_write_format](#) or [set_write_tiles](#).

The main application of this method is to allow an ImageBuf (which by design may hold only a *single* image) to be used for the output of one image of a multi-subimage and/or MIP-mapped image file.

Parameters

- **out** – A pointer to an already-opened [ImageOutput](#) to which the pixels of the ImageBuf will be written.
- **progress_callback/progress_callback_data** – If [progress_callback](#) is non-NULL, the underlying write, if expensive, may make several calls to [progress_callback\(progress_callback_data, portion_done\)](#) which allows you to implement some sort of progress meter.

Returns

true if all went ok, false if there were errors writing.

```
void OIIO::ImageBuf::set_write_format(TypeDesc format)
```

Set the pixel data format that will be used for subsequent [write\(\)](#) calls that do not themselves request a specific data type request.

Note that this does not affect the variety of [write\(\)](#) that takes an open [ImageOutput*](#) as a parameter.

Parameters

format – The data type to be used for all channels.

```
void OIIO::ImageBuf::set_write_format(cspan<TypeDesc> format)
```

Set the per-channel pixel data format that will be used for subsequent [write\(\)](#) calls that do not themselves request a specific data type request.

Parameters

format – The type of each channel (in order). Any channel's format specified as [TypeUnknown](#) will default to be whatever type is described in the [ImageSpec](#) of the buffer.

```
void OIIO::ImageBuf::set_write_tiles(int width = 0, int height = 0, int depth = 0)
```

Override the tile sizing for subsequent calls to the [write\(\)](#) method (the variety that does not take an open [ImageOutput*](#)). Setting all three dimensions to 0 indicates that the output should be a scanline-oriented file.

This lets you write a tiled file from an ImageBuf that may have been read originally from a scanline file, or change the dimensions of a tiled file, or to force the file written to be scanline even if it was originally read from a tiled file.

In all cases, if the file format ultimately written does not support tiling, or the tile dimensions requested, a suitable supported tiling choice will be made automatically.

```
void OIIO::ImageBuf::set_write_ioproxy(Filesystem::IOProxy *ioproxy)
```

Supply an IOProxy to use for a subsequent call to [write\(\)](#).

If a proxy is set but it later turns out that the file format selected does not support write proxies, then `write()` will fail with an error.

9.3 Getting and setting information about an ImageBuf

`bool OIIO::ImageBuf::initialized() const`

Returns `true` if the ImageBuf is initialized, `false` if not yet initialized.

`IBStorage OIIO::ImageBuf::storage() const`

Which type of storage is being used for the pixels? Returns an enumerated type describing the type of storage currently employed by the ImageBuf: `UNINITIALIZED` (no storage), `LOCALBUFFER` (the ImageBuf has allocated and owns the pixel memory), `APPBUFFER` (the ImageBuf “wraps” memory owned by the calling application), or `IMAGECACHE` (the image is backed by an *ImageCache*).

`const ImageSpec &OIIO::ImageBuf::spec() const`

Return a read-only (const) reference to the image spec that describes the buffer.

`const ImageSpec &OIIO::ImageBuf::nativespec() const`

Return a read-only (const) reference to the “native” image spec (that describes the file, which may be slightly different than the spec of the ImageBuf, particularly if the IB is backed by an *ImageCache* that is imposing some particular data format or tile size).

This may differ from `spec()` — for example, if a data format conversion was requested, if the buffer is backed by an *ImageCache* which stores the pixels internally in a different data format than that of the file, or if the file had differing per-channel data formats (ImageBuf must contain a single data format for all channels).

`ImageSpec &OIIO::ImageBuf::specmod()`

Return a writable reference to the *ImageSpec* that describes the buffer. It’s ok to modify most of the metadata, but if you modify the spec’s `format`, `width`, `height`, or `depth` fields, you get the pain you deserve, as the ImageBuf will no longer have correct knowledge of its pixel memory layout. USE WITH EXTREME CAUTION.

`string_view OIIO::ImageBuf::name(void) const`

Returns the name of the buffer (name of the file, for an ImageBuf read from disk).

`string_view OIIO::ImageBuf::file_format_name(void) const`

Return the name of the image file format of the file this ImageBuf refers to (for example “`openexr`”). Returns an empty string for an ImageBuf that was not constructed as a direct reference to a file.

`int OIIO::ImageBuf::subimage() const`

Return the index of the subimage within the file that the ImageBuf refers to. This will always be 0 for an ImageBuf that was not constructed as a direct reference to a file, or if the file contained only one image.

`int OIIO::ImageBuf::nsubimages() const`

Return the number of subimages in the file this ImageBuf refers to, if it can be determined efficiently. This will always be 1 for an ImageBuf that was not constructed as a direct reference to a file, or for an ImageBuf that refers to a file type that is not capable of containing multiple subimages.

Note that a return value of 0 indicates that the number of subimages cannot easily be known without reading the entire image file to discover the total. To compute this yourself, you would need check every subimage successively until you get an error.

`int OIIO::ImageBuf::miplevel() const`

Return the index of the miplevel with a file’s subimage that the ImageBuf is currently holding. This will always be 0 for an ImageBuf that was not constructed as a direct reference to a file, or if the subimage within that file was not MIP-mapped.

int OIIO::ImageBuf::nmiplevels() const

Return the number of MIP levels of the current subimage within the file this ImageBuf refers to. This will always be 1 for an ImageBuf that was not constructed as a direct reference to a file, or if this subimage within the file was not MIP-mapped.

int OIIO::ImageBuf::nchannels() const

Return the number of color channels in the image. This is equivalent to `spec().nchannels`.

int xbegin() const

int xend() const

int ybegin() const

int yend() const

int zbegin() const

int zend() const

Returns the [begin,end) range of the pixel data window of the buffer. These are equivalent to `spec().x`, `spec().x+spec().width`, `spec().y`, `spec().y+spec().height`, `spec().z`, and `spec().z+spec().depth`, respectively.

int OIIO::ImageBuf::orientation() const

Return the current "Orientation" metadata for the image, per the table in `sec-metadata-orientation_`

void OIIO::ImageBuf::set_orientation(int orient)

Set the "Orientation" metadata for the image.

int oriented_width() const

int oriented_height() const

int oriented_x() const

int oriented_y() const

int oriented_full_width() const

int oriented_full_height() const

int oriented_full_x() const

int oriented_full_y() const

The oriented width, height, x, and y describe the pixel data window after taking the display orientation into consideration. The *full* versions the “full” (a.k.a. display) window after taking the display orientation into consideration.

ROI OIIO::ImageBuf::roi() const

Return pixel data window for this ImageBuf as a *ROI*.

ROI OIIO::ImageBuf::roi_full() const

Return full/display window for this ImageBuf as a *ROI*.

void OIIO::ImageBuf::set_origin(int x, int y, int z = 0)

Alters the metadata of the spec in the ImageBuf to reset the “origin” of the pixel data window to be the specified coordinates. This does not affect the size of the pixel data window, only its position.

void OIIO::ImageBuf::set_full(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend)

Set the “full” (a.k.a. display) window to Alters the metadata of the spec in the ImageBuf to reset the “full” image size (a.k.a. “display window”) to

[xbegin,xend) x [ybegin,yend) x [zbegin,zend)

This does not affect the size of the pixel data window.

void OIIO::ImageBuf::set_roi_full(const *ROI* &newroi)

Set full/display window for this ImageBuf to a *ROI*. Does NOT change the channels of the spec, regardless of newroi.

bool OIIO::ImageBuf::contains_roi(const *ROI* &roi) const

Is the specified roi completely contained in the data window of this ImageBuf?

TypeDesc OIIO::ImageBuf::pixeltype() const

The data type of the pixels stored in the buffer (equivalent to *spec().format*).

int OIIO::ImageBuf::threads() const

Retrieve the current thread-spawning policy of this ImageBuf.

void OIIO::ImageBuf::threads(int n) const

Set the threading policy for this ImageBuf, controlling the maximum amount of parallelizing thread “fan-out” that might occur during expensive operations. The default of 0 means that the global attribute(“threads”) value should be used (which itself defaults to using as many threads as cores).

The main reason to change this value is to set it to 1 to indicate that the calling thread should do all the work rather than spawning new threads. That is probably the desired behavior in situations where the calling application has already spawned multiple worker threads.

9.4 Copying ImageBuf’s and blocks of pixels

const ImageBuf &OIIO::ImageBuf::operator=(const ImageBuf &src)

Copy assignment.

const ImageBuf &OIIO::ImageBuf::operator=(ImageBuf &&src)

Move assignment.

bool OIIO::ImageBuf::copy(const ImageBuf &src, *TypeDesc* format = TypeUnknown)

Try to copy the pixels and metadata from src to *this (optionally with an explicit data format conversion).

If the previous state of *this was uninitialized, owning its own local pixel memory, or referring to a read-only image backed by *ImageCache*, then local pixel memory will be allocated to hold the new pixels and the call always succeeds unless the memory cannot be allocated. In this case, the *format* parameter may request a pixel data type that is different from that of the source buffer.

If *this previously referred to an app-owned memory buffer, the memory cannot be re-allocated, so the call will only succeed if the app-owned buffer is already the correct resolution and number of channels. The data type of the pixels will be converted automatically to the data type of the app buffer.

Parameters

- **src** – Another ImageBuf from which to copy the pixels and metadata.
- **format** – Optionally request the pixel data type to be used. The default of *TypeUnknown* means to use whatever data type is used by the *src*. If *this is already initialized and has APPBUFFER storage (“wrapping” an application buffer), this parameter is ignored.

Returns

true upon success or false upon error/failure.

ImageBuf OIIO::ImageBuf::copy(*TypeDesc* format) const

Return a full copy of this ImageBuf (optionally with an explicit data format conversion).

void OIIO::ImageBuf::copy_metadata(const ImageBuf &src)

Copy all the metadata from `src` to `*this` (except for pixel data resolution, channel types and names, and data format).

bool OIIO::ImageBuf::copy_pixels(const ImageBuf &src)

Copy the pixel data from `src` to `*this`, automatically converting to the existing data format of `*this`. It only copies pixels in the overlap regions (and channels) of the two images; pixel data in `*this` that do exist in `src` will be set to 0, and pixel data in `src` that do not exist in `*this` will not be copied.

inline void OIIO::ImageBuf::swap(ImageBuf &other)

Swap the entire contents with another ImageBuf.

9.5 Getting and setting pixel values

Getting and setting individual pixels – slow

float OIIO::ImageBuf::getchannel(int x, int y, int z, int c, WrapMode wrap = WrapBlack) const

Retrieve a single channel of one pixel.

Parameters

- **x/y/z** – The pixel coordinates.
- **c** – The channel index to retrieve. If `c` is not in the valid channel range `0..nchannels-1`, then `getchannel()` will return 0.
- **wrap** – WrapMode that determines the behavior if the pixel coordinates are outside the data window: WrapBlack, WrapClamp, WrapPeriodic, WrapMirror.

Returns

The data value, converted to a float.

inline void OIIO::ImageBuf::getpixel(int x, int y, int z, float *pixel, int maxchannels = 1000, WrapMode wrap = WrapBlack) const

Unsafe version of getpixel using raw pointer. Avoid if possible.

void OIIO::ImageBuf::interpixel(float x, float y, span<float> pixel, WrapMode wrap = WrapBlack) const

Sample the image plane at pixel coordinates (x,y), using linear interpolation between pixels, placing the result in `pixel[0..n-1]` where `n` is the smaller of the span's size and the actual number of channels stored in the buffer.

Parameters

- **x/y** – The pixel coordinates. Note that pixel data values themselves are at the pixel centers, so pixel (i,j) is at image plane coordinate (i+0.5, j+0.5).
- **pixel** – A span giving the location where results will be stored.
- **wrap** – WrapMode that determines the behavior if the pixel coordinates are outside the data window: WrapBlack, WrapClamp, WrapPeriodic, WrapMirror.

void OIIO::ImageBuf::interpixel_bicubic(float x, float y, span<float> pixel, WrapMode wrap = WrapBlack) const

Bicubic interpolation at pixel coordinates (x,y).

void OIIO::ImageBuf::interpixel_NDC(float s, float t, span<float> pixel, WrapMode wrap = WrapBlack) const

Linearly interpolate at NDC coordinates (s,t), where (0,0) is the upper left corner of the display window, (1,1) the lower right corner of the display window.

Note: `interppixel()` uses pixel coordinates (ranging 0..resolution) whereas `interppixel_NDC()` uses NDC coordinates (ranging 0..1).

```
void OIIO::ImageBuf::interppixel_bicubic_NDC(float s, float t, span<float> pixel, WrapMode wrap =
                                         WrapBlack) const
```

Bicubic interpolation at NDC space coordinates (s,t), where (0,0) is the upper left corner of the display (a.k.a. “full”) window, (1,1) the lower right corner of the display window.

```
void OIIO::ImageBuf::setpixel(int x, int y, int z, cspan<float> pixel)
```

Set the pixel with coordinates (x,y,z) to have the values in span `pixel[]`. The number of channels copied is the minimum of the span length and the actual number of channels in the image.

```
inline void OIIO::ImageBuf::setpixel(int i, cspan<float> pixel)
```

Set the *i*-th pixel value of the image (out of width*height*depth), from floating-point values in span `pixel[]`. The number of channels copied is the minimum of the span length and the actual number of channels in the image.

Getting and setting regions of pixels – fast

```
template<typename T>
```

```
inline bool OIIO::ImageBuf::get_pixels(ROI roi, span<T> buffer, stride_t xstride = AutoStride, stride_t ystride =
                                         AutoStride, stride_t zstride = AutoStride) const
```

Retrieve the rectangle of pixels spanning the *ROI* (including channels) at the current subimage and MIP-map level, storing the pixel values into the buffer.

Parameters

- **roi** – The region of interest to copy into. A default uninitialized *ROI* means the entire image.
- **buffer** – A span delineating the extent of the safely accessible memory where the results should be stored.
- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes in the buffer (or `AutoStride` to indicate “contiguous” data in any of those dimensions).

Returns

Return true if the operation could be completed, otherwise return false.

```
template<typename T>
```

```
inline bool OIIO::ImageBuf::get_pixels(ROI roi, span<T> buffer, T *buforigin, stride_t xstride = AutoStride,
                                         stride_t ystride = AutoStride, stride_t zstride = AutoStride) const
```

`get_pixels()` with an extra parameter:

Parameters

buforigin – A pointer to the first pixel of the buffer. If null, it will be assumed to be the beginning of the buffer. This is useful if any negative strides are used to give an unusual layout of pixels within the buffer.

```
template<typename T>
```

```
inline bool OIIO::ImageBuf::set_pixels(ROI roi, span<T> buffer, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)
```

Copy the data into the given *ROI* of the ImageBuf. The data points to values specified by *format*, with layout detailed by the stride values (in bytes, with AutoStride indicating “contiguous” layout). It is up to the caller to ensure that data points to an area of memory big enough to account for the *ROI*. If *roi* is set to *ROI::all()*, the data buffer is assumed to have the same resolution as the ImageBuf itself. Return true if the operation could be completed, otherwise return false. Set the rectangle of pixels within the *ROI* to the values in the *buffer*.

Parameters

- **roi** – The region of interest to copy into. A default uninitialized *ROI* means the entire image.
- **buffer** – A span delineating the extent of the safely accessible memory where the results should be copied from.
- **xstride/ystride/zstride** – The distance in bytes between successive pixels, scanlines, and image planes in the buffer (or AutoStride to indicate “contiguous” data in any of those dimensions).

Returns

Return true if the operation could be completed, otherwise return false.

```
template<typename T>
inline bool OIIO::ImageBuf::set_pixels(ROI roi, span<T> buffer, const T *buforigin, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)
```

set_pixels() with an extra parameter:

Parameters

buforigin – A pointer to the first pixel of the buffer. If null, it will be assumed to be the beginning of the buffer. This is useful if any negative strides are used to give an unusual layout of pixels within the buffer.

9.6 Deep data in an ImageBuf

```
bool OIIO::ImageBuf::deep() const
```

Does this ImageBuf store deep data? Returns true if the ImageBuf holds a “deep” image, false if the ImageBuf holds an ordinary pixel-based image.

```
int OIIO::ImageBuf::deep_samples(int x, int y, int z = 0) const
```

Retrieve the number of deep data samples corresponding to pixel (x,y,z). Return 0 if not a deep image, or if the pixel is outside of the data window, or if the designated pixel has no deep samples.

```
void OIIO::ImageBuf::set_deep_samples(int x, int y, int z, int nsamples)
```

Set the number of deep samples for pixel (x,y,z). If data has already been allocated, this is equivalent to inserting or erasing samples.

```
void OIIO::ImageBuf::deep_insert_samples(int x, int y, int z, int samplepos, int nsamples)
```

Insert nsamples new samples, starting at position samplepos of pixel (x,y,z).

```
void OIIO::ImageBuf::deep_erase_samples(int x, int y, int z, int samplepos, int nsamples)
```

Remove nsamples samples, starting at position samplepos of pixel (x,y,z).

```
float OIIO::ImageBuf::deep_value(int x, int y, int z, int c, int s) const
```

Return the value (as a float) of sample s of channel c of pixel (x,y,z). Return 0 if not a deep image or if the pixel coordinates or channel number are out of range or if that pixel has no deep samples.

```
uint32_t OIIO::ImageBuf::deep_value_uint(int x, int y, int z, int c, int s) const
```

Return the value (as a `uint32_t`) of sample `s` of channel `c` of pixel `(x,y,z)`. Return 0 if not a deep image or if the pixel coordinates or channel number are out of range or if that pixel has no deep samples.

```
void OIIO::ImageBuf::set_deep_value(int x, int y, int z, int c, int s, float value)
```

Set the value of sample `s` of channel `c` of pixel `(x,y,z)` to a `float` value (it is expected that channel `c` is a floating point type).

```
void OIIO::ImageBuf::set_deep_value(int x, int y, int z, int c, int s, uint32_t value)
```

Set the value of sample `s` of channel `c` of pixel `(x,y,z)` to a `uint32_t` value (it is expected that channel `c` is an integer type).

```
const void *OIIO::ImageBuf::deep_pixel_ptr(int x, int y, int z, int c, int s = 0) const
```

Return a pointer to the raw data of pixel `(x,y,z)`, channel `c`, sample `s`. Return `nullptr` if the pixel coordinates or channel number are out of range, if the pixel/channel has no deep samples, or if the image is not deep. Use with caution — these pointers may be invalidated by calls that adjust the number of samples in any pixel.

```
DeepData &OIIO::ImageBuf::deepdata()
```

```
const DeepData &OIIO::ImageBuf::deepdata() const
```

Returns a reference to the underlying `DeepData` for a deep image.

9.7 Error Handling

```
template<typename Str, typename ...Args>
```

```
inline void OIIO::ImageBuf::errorfmt(const Str &fmt, Args&&... args) const
```

Error reporting for `ImageBuf`: call this with `std::format` style formatting specification. It is not necessary to have the error message contain a trailing newline.

```
bool OIIO::ImageBuf::has_error(void) const
```

Returns `true` if the `ImageBuf` has had an error and has an error message ready to retrieve via `geterror()`.

```
std::string OIIO::ImageBuf::geterror(bool clear = true) const
```

Return the text of all pending error messages issued against this `ImageBuf`, and clear the pending error message unless `clear` is false. If no error message is pending, it will return an empty string.

9.8 Miscellaneous

```
void *localpixels()
```

```
const void *localpixels() const
```

Return a raw pointer to the “local” pixel memory, if they are fully in RAM and not backed by an `ImageCache`, or `nullptr` otherwise. You can also test it like a `bool` to find out if pixels are local.

```
void *pixeladdr(int x, int y, int z = 0, int ch = 0)
```

```
const void *pixeladdr(int x, int y, int z = 0, int ch = 0) const
```

Return the address where pixel `(x,y,z)`, channel `ch`, is stored in the image buffer. Use with extreme caution! Will return `nullptr` if the pixel values aren’t local in RAM.

```
int OIIO::ImageBuf::pixelindex(int x, int y, int z, bool check_range = false) const
```

Return the index of pixel `(x,y,z)`. If `check_range` is true, return -1 for an invalid coordinate that is not within the data window.

static WrapMode OIIO::ImageBuf::WrapMode_from_string(string_view name)

Return the WrapMode corresponding to the name ("default", "black", "clamp", "periodic", "mirror"). For an unknown name, this will return WrapDefault.

void lock() const

void unlock() const

Manually lock or unlock the mutex that protects the ImageBuf from concurrent access by multiple threads. Use with caution – this should almost never be needed in ordinary user code.

9.9 Writing your own image processing functions

In this section, we will discuss how to write functions that operate pixel by pixel on an ImageBuf. There are several different approaches to this, with different trade-offs in terms of speed, flexibility, and simplicity of implementation.

9.9.1 Simple pixel-by-pixel access with ImageBufAlgo::perpixel_op()

Pros:

- You only need to supply the inner loop body, the part that does the work for a single pixel.
- You can assume that all pixel data are float values.

Cons/Limitations:

- The operation must be one where each output pixel depends only on the corresponding pixel of the input images.
- Currently, the operation must be unary (one input image to produce one output image), or binary (two input images, one output image). At this time, there are not options to operate on a single image in-place, or to have more than two input images, but this may be extended in the future.
- Operating on float-based images is “full speed,” but if the input images are not float, the automatic conversions will add some expense. In practice, we find working on non-float images to be about half the speed of float images, but this may be acceptable in exchange for the simplicity of this approach, especially for operations where you expect inputs to be float typically.

ImageBuf OIIO::ImageBufAlgo::perpixel_op(const ImageBuf &src, function_view<bool(*span*<float>, *cspan*<float>)> op, KWArgs options = {})

Simple image per-pixel unary operation: Given a source image `src`, return an image of the same dimensions (and same data type, unless `options` includes the “dst_float_pixels” hint turned on, which will result in a float pixel result image) where each pixel is the result of running the caller-supplied function `op` on the corresponding pixel values of `src`. The `op` function should take two `span<float>` arguments, the first referencing a destination pixel, and the second being a reference to the corresponding source pixel. The `op` function should return `true` if the operation was successful, or `false` if there was an error.

The `perpixel_op` function is thread-safe and will parallelize the operation across multiple threads if `nthreads` is not equal to 1 (following the usual ImageBufAlgo `nthreads` rules), and also takes care of all the pixel loops and conversions to and from float values.

The `options` keyword/value list contains additional controls. It supports all hints described by `IBAPrep()` as well as the following:

- “nthreads” : int (default: 0)

Controls the number of threads (0 signalling to use all available threads in the pool).

An example (using the binary op version) of how to implement a simple pixel-by-pixel `add()` operation that is the equivalent of `ImageBufAlgo::add()`:

```
// Assume ImageBuf A, B are the inputs, ImageBuf R is the output
R = ImageBufAlgo::perpixel_op(A, B,
    [](span<float> r, cspan<float> a, cspan<float> b) {
        for (size_t c = 0, nc = size_t(r.size()); c < nc; ++c)
            r[c] = a[c] + b[c];
        return true;
    });
```

Caveats:

- The operation must be one that can be applied independently to each pixel.
- If the input image is not float-valued pixels, there may be some inefficiency due to the need to convert the pixels to float and back, since there is no type templating and thus no opportunity to supply a version of the operation that allows specialization to any other pixel data types

```
ImageBuf OIIO::ImageBufAlgo::perpixel_op(const ImageBuf &srcA, const ImageBuf &srcB,
    function_view<bool(span<float>, cspan<float>, cspan<float>)>
    op, KWArgs options = {})
```

A version of `perpixel_op` that performs a binary operation, taking two source images and a 3-argument `op` function that receives a destination and two source pixels.

Examples:

```
// Assume ImageBuf A, B are the inputs, ImageBuf R is the output

////////////////////////////////////
// Approach 1: using a standalone function to add two images
bool my_add (span<float> r, cspan<float> a, cspan<float> b) {
    for (size_t c = 0, nc = size_t(r.size()); c < nc; ++c)
        r[c] = a[c] + b[c];
    return true;
}

R = ImageBufAlgo::perpixel_op(A, B, my_add);

////////////////////////////////////
// Approach 2: using a "functor" class to add two images
struct Adder {
    bool operator() (span<float> r, cspan<float> a, cspan<float> b) {
        for (size_t c = 0, nc = size_t(r.size()); c < nc; ++c)
            r[c] = a[c] + b[c];
        return true;
    }
};

Adder adder;
R = ImageBufAlgo::perpixel_op(A, B, adder);

(continued from previous page)

```

R = ImageBufAlgo::perpixel_op(A, B,
    [](span<float> r, cspan<float> a, cspan<float> b) {
        for (size_t c = 0, nc = size_t(r.size()); c < nc; ++c)
            r[c] = a[c] + b[c];
        return true;
    });

```

9.10 Iterators – the fast way of accessing individual pixels

Sometimes you need to visit every pixel in an ImageBuf (or at least, every pixel in a large region). Using the `getpixel()` and `setpixel()` for this purpose is simple but very slow. But ImageBuf provides templated `Iterator` and `ConstIterator` types that are very inexpensive and hide all the details of local versus cached storage.

Note: `ImageBuf::ConstIterator` is identical to the `Iterator`, except that `ConstIterator` may be used on a `const ImageBuf` and may not be used to alter the contents of the `ImageBuf`. For simplicity, the remainder of this section will only discuss the `Iterator`.

An `Iterator` is associated with a particular `ImageBuf`. The `Iterator` has a *current pixel* coordinate that it is visiting, and an *iteration range* that describes a rectangular region of pixels that it will visit as it advances. It always starts at the upper left corner of the iteration region. We say that the iterator is *done* after it has visited every pixel in its iteration range. We say that a pixel coordinate *exists* if it is within the pixel data window of the `ImageBuf`. We say that a pixel coordinate is *valid* if it is within the iteration range of the iterator.

The `Iterator<BUFT, USERT>` is templated based on two types: `BUFT` the type of the data stored in the `ImageBuf`, and `USERT` type type of the data that you want to manipulate with your code. `USERT` defaults to `float`, since usually you will want to do all your pixel math with `float`. We will thus use `Iterator<T>` synonymously with `Iterator<T, float>`.

For the remainder of this section, we will assume that you have a `float`-based `ImageBuf`, for example, if it were set up like this:

```

ImageBuf buf ("myfile.exr");
buf.read (0, 0, true, TypeDesc::FLOAT);

```

template<>

Iterator<BUFT>(ImageBuf &buf, WrapMode wrap = WrapDefault)

Initialize an iterator that will visit every pixel in the data window of `buf`, and start it out pointing to the upper left corner of the data window. The `wrap` describes what values will be retrieved if the iterator is positioned outside the data window of the buffer.

template<>

Iterator<BUFT>(ImageBuf &buf, const ROI &roi, WrapMode wrap = WrapDefault)

Initialize an iterator that will visit every pixel of `buf` within the region described by `roi`, and start it out pointing to pixel (`roi.xbegin`, `roi.ybegin`, `roi.zbegin`). The `wrap` describes what values will be retrieved if the iterator is positioned outside the data window of the buffer.

template<>

Iterator<BUFT>(ImageBuf &buf, int x, int y, int z, WrapMode wrap = WrapDefault)

Initialize an iterator that will visit every pixel in the data window of `buf`, and start it out pointing to pixel (`x`, `y`, `z`). The `wrap` describes what values will be retrieved if the iterator is positioned outside the data window of the buffer.

Iterator::operator++()

The ++ operator advances the iterator to the next pixel in its iteration range. (Both prefix and postfix increment operator are supported.)

bool Iterator::done() const

Returns true if the iterator has completed its visit of all pixels in its iteration range.

ROI Iterator::range() const

Returns the iteration range of the iterator, expressed as an ROI.

int Iterator::x() const

int Iterator::y() const

int Iterator::z() const

Returns the x, y, and z pixel coordinates, respectively, of the pixel that the iterator is currently visiting.

bool Iterator::valid() const

Returns true if the iterator's current pixel coordinates are within its iteration range.

bool Iterator::valid(int x, int y, int z = 0) const

Returns true if pixel coordinate (x, y, z) are within the iterator's iteration range (regardless of where the iterator itself is currently pointing).

bool Iterator::exists() const

Returns true if the iterator's current pixel coordinates are within the data window of the ImageBuf.

bool Iterator::exists(int x, int y, int z = 0) const

Returns true if pixel coordinate (x, y, z) are within the pixel data window of the ImageBuf (regardless of where the iterator itself is currently pointing).

USERT &Iterator::operator[] (int i)

The value of channel i of the current pixel. (The wrap mode, set up when the iterator was constructed, determines what value is returned if the iterator points outside the pixel data window of its buffer.)

int Iterator::deep_samples() const

For deep images only, retrieves the number of deep samples for the current pixel.

void Iterator::set_deep_samples()

For deep images only (and non-const ImageBuf), set the number of deep samples for the current pixel. This only is useful if the ImageBuf has not yet had the `deep_alloc()` method called.

USERT Iterator::deep_value(int c, int s) const

uint32_t Iterator::deep_value_int(int c, int s) const

For deep images only, returns the value of channel c, sample number s, at the current pixel.

void Iterator::set_deep_value(int c, int s, float value)

void Iterator::set_deep_value(int c, int s, uint32_t value)

For deep images only (and non-cconst ImageBuf, sets the value of channel c, sample number s, at the current pixel. This only is useful if the ImageBuf has already had the `deep_alloc()` method called.

9.10.1 Example: Visiting all pixels to compute an average color

```

void print_channel_averages (const std::string &filename)
{
    // Set up the ImageBuf and read the file
    ImageBuf buf (filename);
    bool ok = buf.read (0, 0, true, TypeDesc::FLOAT); // Force a float buffer
    if (! ok)
        return;

    // Initialize a vector to contain the running total
    int nc = buf.nchannels();
    std::vector<float> total (n, 0.0f);

    // Iterate over all pixels of the image, summing channels separately
    for (ImageBuf::ConstIterator<float> it (buf); ! it.done(); ++it)
        for (int c = 0; c < nc; ++c)
            total[c] += it[c];

    // Print the averages
    imagesize_t npixels = buf.spec().image_pixels();
    for (int c = 0; c < nc; ++c)
        std::cout << "Channel " << c << " avg = " (total[c] / npixels) << "\n";
}

```

9.10.2 Example: Set all pixels in a region to black

```

bool make_black (ImageBuf &buf, ROI region)
{
    if (buf.spec().format != TypeDesc::FLOAT)
        return false; // Assume it's a float buffer

    // Clamp the region's channel range to the channels in the image
    roi.chend = std::min (roi.chend, buf.nchannels());

    // Iterate over all pixels in the region...
    for (ImageBuf::Iterator<float> it (buf, region); ! it.done(); ++it) {
        if (! it.exists()) // Make sure the iterator is pointing
            continue;     // to a pixel in the data window
        for (int c = roi.chbegin; c < roi.chend; ++c)
            it[c] = 0.0f; // clear the value
    }
    return true;
}

```

9.11 Dealing with buffer data types

The previous section on iterators presented examples and discussion based on the assumption that the ImageBuf was guaranteed to store float data and that you wanted all math to also be done as float computations. Here we will explain how to deal with buffers and files that contain different data types.

9.11.1 Strategy 1: Only have float data in your ImageBuf

When creating your own buffers, make sure they are float:

```
ImageSpec spec (640, 480, 3, TypeDesc::FLOAT); // <-- float buffer
ImageBuf buf ("mybuf", spec);
```

When using ImageCache-backed buffers, force the ImageCache to convert everything to float:

```
// Just do this once, to set up the cache:
ImageCache *cache = ImageCache::create (true /* shared cache */);
cache->attribute ("forcefloat", 1);
...
ImageBuf buf ("myfile.exr"); // Backed by the shared cache
```

Or force the read to convert to float in the buffer if it's not a native type that would automatically stored as a float internally to the ImageCache:¹

```
ImageBuf buf ("myfile.exr"); // Backed by the shared cache
buf.read (0, 0, false /* don't force read to local mem */,
          TypeDesc::FLOAT /* but do force conversion to float*/);
```

Or force a read into local memory unconditionally (rather than relying on the ImageCache), and convert to float:

```
ImageBuf buf ("myfile.exr");
buf.read (0, 0, true /*force read*/,
          TypeDesc::FLOAT /* force conversion */);
```

9.11.2 Strategy 2: Template your iterating functions based on buffer type

Consider the following alternate version of the make_black function from Section *Example: Set all pixels in a region to black*

```
template<typename BUFT>
static bool make_black_impl (ImageBuf &buf, ROI region)
{
    // Clamp the region's channel range to the channels in the image
    roi.chend = std::min (roi.chend, buf.nchannels);

    // Iterate over all pixels in the region...
    for (ImageBuf::Iterator<BUFT> it (buf, region); ! it.done(); ++it) {
        if (! it.exists()) // Make sure the iterator is pointing
            continue;     // to a pixel in the data window
    }
```

(continues on next page)

¹ ImageCache only supports a limited set of types internally, currently float, half, uint8, uint16, and all other data types are converted to these automatically as they are read into the cache.

(continued from previous page)

```

        for (int c = roi.chbegin; c < roi.chend; ++c)
            it[c] = 0.0f; // clear the value
    }
    return true;
}

bool make_black (ImageBuf &buf, ROI region)
{
    if (buf.spec().format == TypeDesc::FLOAT)
        return make_black_impl<float> (buf, region);
    else if (buf.spec().format == TypeDesc::HALF)
        return make_black_impl<half> (buf, region);
    else if (buf.spec().format == TypeDesc::UINT8)
        return make_black_impl<unsigned char> (buf, region);
    else if (buf.spec().format == TypeDesc::UINT16)
        return make_black_impl<unsigned short> (buf, region);
    else {
        buf.error ("Unsupported pixel data format %s", buf.spec().format);
        return false;
    }
}

```

In this example, we make an implementation that is templated on the buffer type, and then a wrapper that calls the appropriate template specialization for each of 4 common types (and logs an error in the buffer for any other types it encounters).

In fact, `imagebufalgo_util.h` provides a macro to do this (and several variants, which will be discussed in more detail in the next chapter). You could rewrite the example even more simply:

```

#include <OpenImageIO/imagebufalgo_util.h>

template<typename BUFT>
static bool make_black_impl (ImageBuf &buf, ROI region)
{
    ... same as before ...
}

bool make_black (ImageBuf &buf, ROI region)
{
    bool ok;
    OIIO_DISPATCH_COMMON_TYPES (ok, "make_black", make_black_impl,
                                buf.spec().format, buf, region);

    return ok;
}

```

This other type-dispatching helper macros will be discussed in more detail in Chapter *ImageBufAlgo: Image Processing*.

IMAGEBUFALGO: IMAGE PROCESSING

ImageBufAlgo is a set of image processing functions that operate on ImageBuf's. The functions are declared in the header file `OpenImageIO/imagebufalgo.h` and are declared in the namespace `ImageBufAlgo`.

10.1 ImageBufAlgo common principles

This section explains the general rules common to all ImageBufAlgo functions. Only exceptions to these rules will be explained in the subsequent listings of all the individual ImageBufAlgo functions.

10.1.1 Return values and error messages

Most ImageBufAlgo functions that produce image data come in two forms:

1. Return an ImageBuf.

The return value is a new ImageBuf containing the result image. In this case, an entirely new image will be created to hold the result. In case of error, the result image returned can have any error conditions checked with `has_error()` and `geterror()`.

C++

```
// Method 1: Return an image result
ImageBuf dst = ImageBufAlgo::over (fg, bg);
if (dst.has_error())
    std::cout << "error: " << dst.geterror() << "\n";
```

Python

```
# Method 1: Return an image result
dst = ImageBufAlgo.over(fg, bg)
if dst.has_error:
    print("error:", dst.geterror())
```

2. Pass a destination ImageBuf reference as the first parameter.

The function is passed a *destination* ImageBuf where the results will be stored, and the return value is a `bool` that is `true` if the function succeeds or `false` if the function fails. Upon failure, the destination ImageBuf (the one that is being altered) will have an error message set.

C++

```
// Method 2: Write into an existing image
ImageBuf dst; // will be the output image
bool ok = ImageBufAlgo::over (dst, fg, bg);
if (! ok)
    std::cout << "error: " << dst.geterror() << "\n";
```

Python

```
# Method 2: Write into an existing image
dst = ImageBuf() # will be the output image
ok = ImageBufAlgo.over(dst, fg, bg)
if not ok:
    print("error:", dst.geterror())
```

The first option (return an ImageBuf directly) is a more compact and intuitive notation that is natural for most simple uses. But the second option (pass an ImageBuf& referring to an existing destination) offers additional flexibility, including more careful control over allocations, the ability to partially overwrite regions of an existing image, and the ability for the destination image to also be one of the input images (for example, `add(A,A,B)` adds B into existing image A, with no third image allocated at all).

For a small minority of ImageBufAlgo functions, there are only input images, and no image outputs (e.g., `isMonochrome()`). In such cases, the error message should be retrieved from the first input image.

10.1.2 Region of interest

Most ImageBufAlgo functions take an optional ROI parameter that restricts the operation to a range in x, y, z, and channels. The default-constructed ROI (also known as `ROI::All()`) means no region restriction – the whole image will be copied or altered.

For ImageBufAlgo functions that write into a destination ImageBuf parameter and it is already initialized (i.e. allocated with a particular size and data type), the operation will be performed on the pixels in the destination that overlap the ROI, leaving pixels in the destination which are outside the ROI unaltered.

For ImageBufAlgo functions that return an ImageBuf directly, or if their `dst` parameter is an uninitialized ImageBuf, the ROI (if set) determines the size of the result image. If the ROI is the default `All`, the result image size will be the union of the pixel data windows of the input images and have a data type determined by the data types of the input images.

Most ImageBufAlgo functions also respect the `chbegin` and `chend` members of the ROI, thus restricting the channel range on which the operation is performed. The default ROI constructor sets up the ROI to specify that the operation should be performed on all channels of the input image(s).

10.1.3 Constant and per-channel values

Many ImageBufAlgo functions take per-channel constant-valued arguments (for example, a fill color). These parameters are passed as `cspan<float>`. These are generally expected to have length equal to the number of channels. But you may also pass a single float which will be used as the value for all channels. (More generally, what is happening is that the last value supplied is replicated for any missing channel.)

Some ImageBufAlgo functions have parameters of type `Image_or_Const`, which may take either an ImageBuf reference, or a per-channel constant, or a single constant to be used for all channels.

10.1.4 Multithreading

All ImageBufAlgo functions take an optional `nthreads` parameter that signifies the maximum number of threads to use to parallelize the operation. The default value for `nthreads` is 0, which signifies that the number of thread should be the OIIO global default set by `OIIO::attribute()` (see Section *Global Attributes*), which itself defaults to be the detected level of hardware concurrency (number of cores available).

Generally you can ignore this parameter (or pass 0), meaning to use all the cores available in order to perform the computation as quickly as possible. The main reason to explicitly pass a different number (generally 1) is if the application is multithreaded at a high level, and the thread calling the ImageBufAlgo function just wants to continue doing the computation without spawning additional threads, which might tend to crowd out the other application threads.

10.2 Pattern generation

For the ImageBufAlgo functions in this section, there is no “source” image. Therefore, either an initialized `dst` must be supplied (to give a pre-allocated size and data type of the image), or else it is strictly necessary to supply an ROI parameter to specify the size of the new image (the data type in this case will always be `float`). It is an error if one of the pattern generation ImageBufAlgo functions is neither supplied a pre-allocated `dst` nor a non-default ROI.

10.2.1 zero() – create a black image

ImageBuf OIIO::ImageBufAlgo::**zero**(ROI roi, int nthreads = 0)

Create an all-black `float` image of size and channels as described by the *ROI*.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::zero(ImageBuf &dst, ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
// Create a new 3-channel, 512x512 float image filled with 0.0 values.
ImageBuf zero = ImageBufAlgo::zero (ROI(0,512,0,512,0,1,0,3));

// Zero out an existing buffer, keeping it the same size and data type
ImageBufAlgo::zero (A);

// Zero out just the green channel, leave everything else the same
ROI roi = B.roi ();
roi.chbegin = 1; // green
roi.chend = 2;   // one past the end of the channel region
ImageBufAlgo::zero (B, roi);

// Zero out a rectangular region of an existing buffer
ImageBufAlgo::zero (C, ROI (0, 100, 0, 100));
```

Python

```
# Create a new 3-channel, 512x512 float image filled with 0.0 values.
zero = ImageBufAlgo.zero(ROI(0, 512, 0, 512, 0, 1, 0, 3))
```

(continues on next page)

(continued from previous page)

```
# Zero out an existing buffer, keeping it the same size and data type
ImageBufAlgo.zero(A)

# Zero out just the green channel, leave everything else the same
roi = B.roi
roi.chbegin = 1 # green
roi.chend = 2   # one past the end of the channel region
ImageBufAlgo.zero(B, roi)

# Zero out a rectangular region of an existing buffer
ImageBufAlgo.zero(C, ROI(0, 100, 0, 100))
```

oiiotool

```
# Create a new 3-channel, 512x512 float image filled with 0.0 values.
oiiotool --create 512x512 3 -d float -o out.exr

# Zero out an existing image, keeping it the same size and data type.
# For simplicity, just scale all values by 0.0
oiiotool in.exr --mulc 0.0 -o out.exr

# Zero out just the green channel, leave everything else the same.
# Again, rely on --mulc to scale the channels
oiiotool in.exr --mulc 1,0,1 -o out.exr

# Zero out a rectangular region of an existing image
oiiotool in.exr --fill:color=0,0,0 100x100+0+0 -o out.exr
```

10.2.2 fill() – fill a region with a solid color or gradient

group fill

Fill an image region with given channel values, either returning a new image or altering the existing `dst` image within the *ROI*. Note that the values arrays start with channel 0, even if the *ROI* indicates that a later channel is the first to be changed.

Three varieties of *fill()* exist: (a) a single set of channel values that will apply to the whole *ROI*, (b) two sets of values that will create a linearly interpolated gradient from top to bottom of the *ROI*, (c) four sets of values that will be bilinearly interpolated across all four corners of the *ROI*.

Functions

ImageBuf **fill**(*cspan*<float> values, ROI roi, int nthreads = 0)

ImageBuf **fill**(*cspan*<float> top, *cspan*<float> bottom, ROI roi, int nthreads = 0)

ImageBuf **fill**(*cspan*<float> topleft, *cspan*<float> topright, *cspan*<float> bottomleft, *cspan*<float> bottomright, ROI roi, int nthreads = 0)

bool **fill**(ImageBuf &dst, *cspan*<float> values, ROI roi = {}, int nthreads = 0)

bool **fill**(ImageBuf &dst, *cspan*<float> top, *cspan*<float> bottom, ROI roi = {}, int nthreads = 0)

bool **fill**(ImageBuf &dst, *cspan*<float> topleft, *cspan*<float> topright, *cspan*<float> bottomleft, *cspan*<float> bottomright, ROI roi = {}, int nthreads = 0)

Examples:

C++

```
// Create a new 640x480 RGB image, with a top-to-bottom gradient
// from red to pink
float pink[3] = { 1, 0.7, 0.7 };
float red[3]  = { 1, 0, 0 };
ImageBuf A    = ImageBufAlgo::fill(red, cspan<float>(pink),
                                   ROI(0, 640, 0, 480, 0, 1, 0, 3));

// Draw a filled red rectangle overtop existing image A.
ImageBufAlgo::fill (A, cspan<float>(red), ROI(50, 100, 75, 175));
```

Python

```
# Create a new 640x480 RGB image, with a top-to-bottom gradient
# from red to pink
pink = (1, 0.7, 0.7)
red = (1, 0, 0)
A = ImageBufAlgo.fill(top=red, bottom=pink,
                      roi=ROI(0, 640, 0, 480, 0, 1, 0, 3))

# Draw a filled red rectangle overtop existing image A.
ImageBufAlgo.fill(A, red, ROI(50, 100, 75, 175))
```

oiiotool

```
# Create a new 640x480 RGB image, with a top-to-bottom gradient
# from red to pink
oiiotool --pattern fill:top=1,0.7,0.7:bottom=1,0,0 640x480 3 -o A.exr

# Draw a filled red rectangle overtop existing image A.exr
oiiotool A.exr --pattern fill:color=1,0,0 25x75 3 --paste +50+100 -o A.
↪.exr
```

10.2.3 checker() – make a checker pattern

ImageBuf OIIO::ImageBufAlgo::**checker**(int width, int height, int depth, *cspan*<float> color1, *cspan*<float> color2, int xoffset, int yoffset, int zoffset, *ROI* roi, int nthreads = 0)

Create a checkerboard pattern of size given by *roi*, with origin given by the *offset* values, checker size given by the *width*, *height*, *depth* values, and alternating between *color1*[] and *color2* []. The pattern is defined in abstract “image space” independently of the pixel data window of *dst* or the *ROI*.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::checker(ImageBuf &dst, int width, int height, int depth,
                                   cspan<float> color1, cspan<float> color2, int
                                   xoffset = 0, int yoffset = 0, int zoffset = 0, ROI roi =
                                   {}, int nthreads = 0)
```

Write to an existing image *dst* (allocating if it is uninitialized).

Examples:

C++

```
// Create a new 640x480 RGB image, fill it with a two-toned gray
// checkerboard, the checkers being 64x64 pixels each.
ImageBuf A(ImageSpec(640, 480, 3, TypeDesc::FLOAT));
float dark[3] = { 0.1, 0.1, 0.1 };
float light[3] = { 0.4, 0.4, 0.4 };
ImageBufAlgo::checker(A, 64, 64, 1, cspan<float>(dark), cspan<float>
↳(light),
                      0, 0, 0);
```

Python

```
# Create a new 640x480 RGB image, fill it with a two-toned gray
# checkerboard, the checkers being 64x64 pixels each.
A = ImageBuf(ImageSpec(640, 480, 3, "float"))
dark = (0.1, 0.1, 0.1)
light = (0.4, 0.4, 0.4)
A = ImageBufAlgo.checker(64, 64, 1, dark, light,
                          roi=ROI(0, 640, 0, 480, 0, 1, 0, 3))
```

oiio tool

```
# Create a new 640x480 RGB image, fill it with a two-toned gray
# checkerboard, the checkers being 64x64 pixels each.
oiiotool --pattern checker:width=64:color1=0.1,0.1,0.1:color2=0.4,0.4,
↪0.4 640x480 3 -o A.exr
```

10.2.4 Noise patterns

`ImageBuf OIIO::ImageBufAlgo::noise`(string_view noisetype, float A = 0.0f, float B = 0.1f, bool mono = false, int seed = 0, *ROI* roi = {}, int nthreads = 0)

Return an image of “noise” in every pixel and channel specified by the roi. There are several noise types to choose from, and each behaves differently and has a different interpretation of the A and B parameters:

- “gaussian” adds Gaussian (normal distribution) noise values with mean value A and standard deviation B.
- “white” adds independent uniformly distributed values on range [A,B).
- “uniform” (synonym for “white”)
- “blue” adds “blue noise” uniformly distributed on range [A,B) but not independent; rather, they are chosen for good spectral properties for sampling and dither.
- “salt” changes to value A a portion of pixels given by B.

If the `mono` flag is true, a single noise value will be applied to all channels specified by `roi`, but if `mono` is false, a separate noise value will be computed for each channel in the region.

The random number generator is actually driven by a hash on the “image

space” coordinates and channel, independently of the pixel data window of `dst` or the *ROI*. Choosing different seed values will result in a different pattern, but for the same seed value, the noise at a given pixel coordinate (x,y,z) channel c will be completely deterministic and repeatable.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::noise(ImageBuf &dst, string_view noisetype, float A = 0.0f,
                                float B = 0.1f, bool mono = false, int seed = 0, ROI roi
                                = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
// Create a new 256x256 field of grayscale white noise on [0,1)
ImageBuf A = ImageBufAlgo::noise ("uniform", 0.0f /*min*/, 1.0f /*max*/,
    ↪,
    true /*mono*/, 1 /*seed*/, ROI(0,256,
    ↪0,256,0,1,0,3));

// Create a new 256x256 field of grayscale white noise on [0,1)
ImageBuf B = ImageBufAlgo::noise ("blue", 0.0f /*min*/, 1.0f /*max*/,
    true /*mono*/, 1 /*seed*/, ROI(0,256,
    ↪0,256,0,1,0,3));

// Add color Gaussian noise to an existing image
ImageBuf C ("tahoe.tif");
ImageBufAlgo::noise (C, "gaussian", 0.0f /*mean*/, 0.1f /*stddev*/,
    false /*mono*/, 1 /*seed*/);

// Use salt and pepper noise to make occasional random dropouts
ImageBuf D ("tahoe.tif");
ImageBufAlgo::noise (D, "salt", 0.0f /*value*/, 0.01f /*portion*/,
    true /*mono*/, 1 /*seed*/);
```

Python

```
# Create a new 256x256 field of grayscale white noise on [0,1)
A = ImageBufAlgo.noise("uniform", A=0.0, B=1.0, mono=True, seed=1,
                        roi=ROI(0, 256, 0, 256, 0, 1, 0, 3))

# Create a new 256x256 field of grayscale blue noise on [0,1)
B = ImageBufAlgo.noise("blue", A=0.0, B=1.0, mono=True, seed=1,
                        roi=ROI(0, 256, 0, 256, 0, 1, 0, 3))

# Add color Gaussian noise to an existing image
C = ImageBuf("tahoe.tif")
ImageBufAlgo.noise(C, "gaussian", A=0.0, B=0.1, mono=False, seed=1)

# Use salt and pepper noise to make occasional random dropouts
D = ImageBuf("tahoe.tif")
ImageBufAlgo.noise(D, "salt", A=0.0, B=0.01, mono=True, seed=1)
```

oiiotool

```
# Create a new 256x256 field of grayscale white noise on [0,1)
oiiotool --pattern noise:type=uniform:mono=1:seed=1 256x256 3 -o A.exr

# Create a new 256x256 field of grayscale blue noise on [0,1)
oiiotool --pattern noise:type=blue:mono=1:seed=1 256x256 3 -o B.exr

# Add color Gaussian noise to an existing image
```

(continues on next page)

(continued from previous page)

```
oiiotool tahoe.jpg --noise:type=gaussian:stddev=0.1 -o C.exr

# Use salt and pepper noise to make occasional random dropouts
oiiotool tahoe.jpg --noise:type=salt:value=0:portion=0.01:mono=1 -o D.
↪ exr
```

```
const ImageBuf &OIIO::ImageBufAlgo::bluenoise_image()
```

Return a const reference to a periodic bluenoise texture with float data in 4 channels that are uncorrelated to each other. Note that unlike most other ImageBufAlgo functions, it does not return an ImageBuf by value, but by const reference.

Example:

C++

```
const ImageBuf& A = ImageBufAlgo::bluenoise_image();
```

Python

```
A = ImageBufAlgo.bluenoise_image()
```

10.2.5 Drawing shapes: points, lines, boxes

```
bool OIIO::ImageBufAlgo::render_point(ImageBuf &dst, int x, int y, cspan<float> color = 1.0f, ROI roi = {},
                                     int nthreads = 0)
```

Render a single point at (x,y) of the given color “over” the existing image dst. If there is no alpha channel, the color will be written unconditionally (as if the alpha is 1.0).

Examples:

C++

```
ImageBuf A (ImageSpec (640, 480, 4, TypeDesc::FLOAT));
float red[4] = { 1, 0, 0, 1 };
ImageBufAlgo::render_point (A, 50, 100, red);
```

Python

```
A = ImageBuf(ImageSpec(640, 480, 4, "float"))
red = (1, 0, 0, 1)
ImageBufAlgo.render_point(A, 50, 100, red)
```

oiitool

```
oiitool A.exr -point:color=1,0,0,1 50,100 -o out.exr
```

```
bool OIIO::ImageBufAlgo::render_line(ImageBuf &dst, int x1, int y1, int x2, int y2, cspan<float> color =
1.0f, bool skip_first_point = false, ROI roi = {}, int nthreads = 0)
```

Render a line from pixel (x1,y1) to (x2,y2) into dst, doing an “over” of the color (if it includes an alpha channel) onto the existing data in dst. The color should include as many values as roi.chend-1. The ROI can be used to limit the pixel area or channels that are modified, and default to the entirety of dst. If skip_first_point is true, the first point (x1, y1) will not be drawn (this can be helpful when drawing poly-lines, to avoid double-rendering of the vertex positions).

Examples:

C++

```
ImageBuf A (ImageSpec (640, 480, 4, TypeDesc::FLOAT));
float red[4] = { 1, 0, 0, 1 };
ImageBufAlgo::render_line (A, 10, 60, 250, 20, red);
ImageBufAlgo::render_line (A, 250, 20, 100, 190, red, true);
```

Python

```
A = ImageBuf(ImageSpec(640, 480, 4, "float"))
red = (1, 0, 0, 1)
ImageBufAlgo.render_line(A, 10, 60, 250, 20, red)
ImageBufAlgo.render_line(A, 250, 20, 100, 190, red, True)
```

oiitool

```
oiitool A.exr -line:color=1,0,0,1 10,60,250,20,100 -o out.exr
```

```
bool OIIO::ImageBufAlgo::render_box(ImageBuf &dst, int x1, int y1, int x2, int y2, cspan<float> color = 1.0f,
                                     bool fill = false, ROI roi = {}, int nthreads = 0)
```

Render a filled or unfilled box with corners at pixels (x1,y1) and (x2,y2) into dst, doing an “over” of the color (if it includes an alpha channel) onto the existing data in dst. The color must include as many values as `roi.chend-1`. The *ROI* can be used to limit the pixel area or channels that are modified, and default to the entirety of dst. If fill is true, the box will be completely filled in, otherwise only its outline will be drawn.

Examples:

C++

```
ImageBuf A (ImageSpec (640, 480, 4, TypeDesc::FLOAT));
float cyan[4] = { 0, 1, 1, 1 };
float yellow_transparent[4] = { 0.5, 0.5, 0, 0.5 };
ImageBufAlgo::render_box (A, 150, 100, 240, 180, cyan);
ImageBufAlgo::render_box (A, 100, 50, 180, 140, yellow_transparent,
↳ true);
```

Python

```
A = ImageBuf(ImageSpec(640, 480, 4, "float"))
cyan = (0, 1, 1, 1)
yellow_transparent = (0.5, 0.5, 0, 0.5)
ImageBufAlgo.render_box(A, 150, 100, 240, 180, cyan)
ImageBufAlgo.render_box(A, 100, 50, 180, 140, yellow_transparent,
↳ fill=True)
```

oiitool

```
oiitool A.exr -box:color=0,1,1,1 150,100,240,180 \
          -box:color=0.5,0.5,0,0.5 100,50,180,140 -o out.exr
```

10.2.6 Drawing text

```
bool OIIO::ImageBufAlgo::render_text(ImageBuf &dst, int x, int y, string_view text, int fontsize = 16,
                                     string_view fontname = "", cspan<float> textcolor = 1.0f, TextAlignX
                                     alignx = TextAlignX::Left, TextAlignY aligny =
                                     TextAlignY::Baseline, int shadow = 0, ROI roi = {}, int nthreads = 0)
```

Render a text string (encoded as UTF-8) into image `dst`. If the `dst` image is not yet initialized, it will be initialized to be a black background exactly large enough to contain the rasterized text. If `dst` is already initialized, the text will be rendered into the existing image by essentially doing an “over” of the character into the existing pixel data.

Note that any named fonts (if not a full pathname) will search for the fonts in the following places: (a) any directories named in the global “font_searchpath” attribute or the `$OPENIMAGEIO_FONTS` environment variable; (b) any font-related subdirectories (`fonts`, `Fonts`, `share/fonts`, or `Library/Fonts`) underneath the directories in environment variables `$HOME`, `$SystemRoot`, `$OpenImageIO_ROOT`; (c) a number of common system font areas, including `/usr/share/fonts`, `/Library/fonts`, and `C:/Windows/fonts`; (d) in fonts directories one level up from the place where the currently running binary lives.

Parameters

- **dst** – Destination ImageBuf; text is rendered into this image.
- **x/y** – The position to place the text.
- **text** – The text to draw. Linefeed (`\n`) characters are respected as indications that the text spans multiple rows.
- **fontsize/fontname** – Size and name of the font. If the name is not a full pathname to a font file, it will search for a matching font, defaulting to some reasonable system font if not supplied at all), and with a nominal height of `fontsize` (in pixels).
- **textcolor** – Color for drawing the text, defaulting to opaque white (1.0,1.0,...) in all channels if not supplied. If provided, it is expected to point to a float array of length at least equal to `R.spec().nchannels`, or defaults will be chosen for you).
- **alignx/aligny** – The default behavior is to align the left edge of the character baseline to (x,y). Optionally, `alignx` and `aligny` can override the alignment behavior, with horizontal alignment choices of `TextAlignX::Left`, `Right`, and `Center`, and vertical alignment choices of `Baseline`, `Top`, `Bottom`, or `Center`.
- **shadow** – If nonzero, a “drop shadow” of this radius will be used to make the text look more clear by dilating the alpha channel of the composite (makes a black halo around the characters).

Examples:

C++

```
ImageBufAlgo::render_text(ImgA, 50, 100, "Hello, world");
float red[] = { 1, 0, 0, 1 };
ImageBufAlgo::render_text(ImgA, 100, 200, "Go Big Red!", 60,
                          "" /*font name*/, cspan<float>(red));

float white[] = { 1, 1, 1, 1 };
ImageBufAlgo::render_text(ImgB, 320, 240, "Centered", 60, "" /*font_
↪name*/,
                          cspan<float>(white),
```

(continues on next page)

(continued from previous page)

```
ImageBufAlgo::TextAlignX::Center,
ImageBufAlgo::TextAlignY::Center);
```

Python

```
ImageBufAlgo.render_text(ImgA, 50, 100, "Hello, world")
red = (1, 0, 0, 1)
ImageBufAlgo.render_text(ImgA, 100, 200, "Go Big Red!",
                          fontsize=60, fontname="", textcolor=red)

white = (1, 1, 1, 1)
ImageBufAlgo.render_text(ImgB, 320, 240, "Centered",
                          fontsize=60, fontname="", textcolor=white,
                          alignx="center", aligny="center")
```

oiiotool

```
oiiotool ImgA.exr --text:x=50:y=100 "Hello, world" \
  --text:x=100:y=200:fontsize=60:fontname="Arial Bold":color=1,0,0,1
↪ "Go Big Red!" \
  -o out.exr

oiiotool ImgB.exr \
  --text:x=320:y=240:fontsize=60:fontname="Arial Bold":color=1,1,1,
↪ 1:alignx=center:aligny=center "Centered" \
  -o out.exr
```

ROI `OIIO::ImageBufAlgo::text_size(string_view text, int fontsize = 16, string_view fontname = "")`

The helper function `text_size()` merely computes the dimensions of the text, returning it as an *ROI* relative to the left side of the baseline of the first character. Only the *x* and *y* dimensions of the *ROI* will be used. The *x* dimension runs from left to right, and *y* runs from top to bottom (image coordinates). For a failure (such as an invalid font name), the *ROI* will return false if you call its `defined()` method. The text may contain linefeed characters to designate multiple lines of text.

Examples:

C++

```
// Render text centered in the image, using text_size to find out
// the size we will need and adjusting the coordinates.
ImageBuf A (ImageSpec (640, 480, 4, TypeDesc::FLOAT));
ROI Aroi = A.roi();
ROI size = ImageBufAlgo::text_size("Centered", 48, "Courier New");
if (size.defined()) {
    int x = Aroi.xbegin + Aroi.width()/2 - (size.xbegin + size.
    width()/2);
    int y = Aroi.ybegin + Aroi.height()/2 - (size.ybegin + size.
    height()/2);
    ImageBufAlgo::render_text(A, x, y, "Centered", 48, "Courier New");
}
```

Python

```
# Render text centered in the image, using text_size to find out
# the size we will need and adjusting the coordinates.
A = ImageBuf(ImageSpec(640, 480, 4, "float"))
Aroi = A.roi
size = ImageBufAlgo.text_size("Centered", 48, "Courier New")
if size.defined:
    x = Aroi.xbegin + Aroi.width//2 - (size.xbegin + size.width//2)
    y = Aroi.ybegin + Aroi.height//2 - (size.ybegin + size.height//2)
    ImageBufAlgo.render_text(A, x, y, "Centered", 48, "Courier New")
```

10.3 Image transformations and data movement

10.3.1 Shuffling channels

`ImageBuf OIII::ImageBufAlgo::channels`(const `ImageBuf &src`, int `nchannels`, *`cspan`*<int> `channelorder`, *`cspan`*<float> `channelvalues` = {}, *`cspan`*<std::string> `newchannelnames` = {}, bool `shuffle_channel_names` = false, int `nthreads` = 0)

Generic channel shuffling: return (or store in `dst`) a copy of `src`, but with channels in the order `channelorder[0..nchannels-1]` (or set to a constant value, designated by `channelorder[i] = -1` and having the fill value in `channelvalues[i]`). In-place operation is allowed (i.e., `dst` and `src` the same image, but an extra copy will occur).

Parameters

- **`nchannels`** – The total number of channels that will be set up in the `dst` image.
- **`channelorder`** – For each channel in `dst`, the index of the `src` channel from which to copy. Any `channelorder[i] < 0` indicates that the channel `i` should be filled with constant value `channelvalues[i]` rather than copy any channel from `src`. If `channelorder` itself is empty, the implied channel order will be {0, 1, ..., `nchannels-1`}, meaning that it's only renaming, truncating, or extending channels, not reordering the channels that are already present.
- **`channelvalues`** – Fill values for color channels in which `channelorder[i] < 0`. This can be empty if no channels are to be filled with constant values.

- **newchannelnames** – An array of new channel names. Channels for which this specifies an empty string will have their name taken from the `src` channel that was copied. If `newchannelnames` is entirely empty, all channel names will simply be copied from `src`.
- **shuffle_channel_names** – If true, the channel names will be taken from the corresponding channels of the source image — be careful with this, shuffling both channel ordering and their names could result in no semantic change at all, if you catch the drift. If false (the default), the resulting `dst` image will have default channel names in the usual order (“R”, “G”, etc.).

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::channels(ImageBuf &dst, const ImageBuf &src, int
                                nchannels, cspan<int> channelorder, cspan<float>
                                channelvalues = {}, cspan<std::string>
                                newchannelnames = {}, bool
                                shuffle_channel_names = false, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
// Copy the first 3 channels of an RGBA, drop the alpha
ImageBuf RGB = ImageBufAlgo::channels(RGBA, 3, {} /*default ordering*/
↪);

// Copy just the alpha channel, making a 1-channel image
ImageBuf Alpha = ImageBufAlgo::channels(RGBA, 1, 3 /*alpha_channel*/);

// Swap the R and B channels
ImageBuf BRGA;
bool success = ImageBufAlgo::channels(BRGA, RGBA, 4, { 2, 1, 0, 3 }, {}
↪,
                                { "R", "G", "B", "A" });

// Add an alpha channel with value 1.0 everywhere to an RGB image,
// keep the other channels with their old ordering, values, and
// names.
RGBA = ImageBufAlgo::channels(RGB, 4, { 0, 1, 2, -1 },
                                { 0 /*ignore*/, 0 /*ignore*/, 0 /
↪/*ignore*/,
                                1.0 },
                                { "", "", "", "A" });
```

Python

```
# Copy the first 3 channels of an RGBA, drop the alpha
RGB = ImageBufAlgo.channels(RGBA, (0, 1, 2))

# Copy just the alpha channel, making a 1-channel image
Alpha = ImageBufAlgo.channels(RGBA, ("A",))

# Swap the R and B channels
success = ImageBufAlgo.channels(BRGA, RGBA,
                                channelorder=(2, 1, 0, 3),
```

(continues on next page)

(continued from previous page)

```

newchannelnames=("R", "G", "B", "A"))

# Add an alpha channel with value 1.0 everywhere to an RGB image,
# keep the other channels with their old ordering, values, and
# names.
RGBA = ImageBufAlgo.channels(RGB,
                             channelorder=(0, 1, 2, 1.0),
                             newchannelnames=(" ", " ", " ", "A"))

```

oiiotool

```

# Copy the first 3 channels of an RGBA, drop the alpha
oiiotool RGBA.exr -ch R,G,B -o RGB.exr

# Copy just the alpha channel, making a 1-channel image
oiiotool RGBA.exr -ch A -o A.exr

# Swap the R and B channels
oiiotool RGBA.exr -ch R=B,G=B,R,A -o BGRA.exr

# Add an alpha channel with value 1.0 everywhere to an RGB image,
# keep the other channels with their old ordering, values, and
# names.
oiiotool RGB.exr -ch 0,1,2,1.0 -o RGBA.exr

```

ImageBuf OIIO::ImageBufAlgo::channel_append(const ImageBuf &A, const ImageBuf &B, *ROI* roi = {}, int nthreads = 0)

Append the channels of A and B together into dst over the region of interest. If the region passed is uninitialized (the default), it will be interpreted as being the union of the pixel windows of A and B (and all channels of both images). If dst is not already initialized, it will be resized to be big enough for the region.

Result-as-parameter version:

```

bool OIIO::ImageBufAlgo::channel_append(ImageBuf &dst, const ImageBuf &A,
                                         const ImageBuf &B, ROI roi = {}, int
                                         nthreads = 0)

```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```

ImageBuf RGBA("grid.exr");
ImageBuf RGBAZ = ImageBufAlgo::channel_append(RGBA, Z);

```

Python

```

RGBA = ImageBuf("grid.exr")
RGBAZ = ImageBufAlgo.channel_append(RGBA, Z)

```

oiitool

```
oiitool rgba.exr z.exr --chappend -o rgbaz.exr
```

`ImageBuf OIIO::ImageBufAlgo::copy`(const `ImageBuf` &src, *TypeDesc* convert = `TypeUnknown`, *ROI* roi = {}, int nthreads = 0)

Return the specified region of pixels of `src` as specified by `roi` (which will default to the whole of `src`, optionally with the pixel type overridden by `convert` (if it is not `TypeUnknown`).

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::copy(ImageBuf &dst, const ImageBuf &src, TypeDesc
                             convert = TypeUnknown, ROI roi = {}, int nthreads =
                             0)
```

Write to an existing image `dst` (allocating if it is uninitialized). If `dst` is not already initialized, it will be set to the same size as `roi` (defaulting to all of `src`)

Examples:

C++

```
// Set B to be a copy of A, but converted to float
ImageBuf A("grid.exr");
ImageBuf B = ImageBufAlgo::copy(A, TypeDesc::FLOAT);
```

Python

```
# Set B to be a copy of A, but converted to float
A = ImageBuf("grid.exr")
B = ImageBufAlgo.copy(A, convert="float")
```

oiitool

```
# Convert A to float pixels
oiitool A.exr -d float -o B.exr
```

`ImageBuf OIIO::ImageBufAlgo::crop`(const `ImageBuf` &src, *ROI* roi = {}, int nthreads = 0)

Return the specified region of `src` as an image, without altering its position in the image plane.

Pixels from `src` which are outside `roi` will not be copied, and new black pixels will be added for regions of `roi` which were outside the data window of `src`.

Note that the `crop` operation does not actually move the pixels on the image plane or adjust the full/display window; it merely restricts which pixels are copied from `src` to `dst`. (Note the difference compared to `cut()`).

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::crop(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int
                               nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
// Set B to be a 200x100 region of A starting at (50,50), trimming
// the exterior away but leaving that region in its original position.
ImageBuf A("grid.exr");
ImageBuf B = ImageBufAlgo::crop(A, ROI(50, 250, 50, 150));
```

Python

```
# Set B to be a 200x100 region of A starting at (50,50), trimming
# the exterior away but leaving that region in its original position.
A = ImageBuf("grid.exr")
B = ImageBufAlgo.crop(A, ROI(50, 250, 50, 150))
```

oiitool

```
# Set B to be a 200x100 region of A starting at (50,50), trimming
# the exterior away but leaving that region in its original position.
oiitool A.exr --crop 200x100+50+50 -o B.exr
```

ImageBuf OIIO::ImageBufAlgo::cut(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Return the designated region of src, but repositioned to the image origin and with the full/display window set to exactly cover the new pixel data window. (Note the difference compared to `crop()`).

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::cut(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int
                               nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
// Set B to be a 200x100 region of A starting at (50,50), but
// moved to the upper left corner so its new origin is (0,0).
ImageBuf A("grid.exr");
ImageBuf B = ImageBufAlgo::cut(A, ROI(50, 250, 50, 150));
```

Python

```
# Set B to be a 200x100 region of A starting at (50,50), but
# moved to the upper left corner so its new origin is (0,0).
A = ImageBuf("grid.exr")
B = ImageBufAlgo.cut(A, ROI(50, 250, 50, 150))
```

oiitool

```
# Set B to be a 200x100 region of A starting at (50,50), but
# moved to the upper left corner so its new origin is (0,0).
oiiotool A.exr --cut 200x100+50+50 -o B.exr
```

bool OIIO::ImageBufAlgo::paste(ImageBuf &dst, int xbegin, int ybegin, int zbegin, int chbegin, const ImageBuf &src, ROI srcroi = {}, int nthreads = 0)

Copy src pixels within srcroi into the dst image, offset so that source location (0,0,0) will be copied to destination location (xbegin,ybegin,zbegin). If the srcroi is *ROI::All()*, the entirety of the data window of src will be used. It will copy into channels[chbegin...], as many channels as are described by srcroi. Pixels or channels of src inside srcroi will replace the corresponding destination pixels entirely, whereas src pixels outside of srcroi will not be copied and the corresponding offset pixels of dst will not be altered.

Examples:

C++

```
// Paste Fg on top of Bg, offset by (100,100)
ImageBuf Bg("grid.exr");
ImageBuf Fg("tahoe.tif");
ImageBufAlgo::paste(Bg, 100, 100, 0, 0, Fg);
```

Python

```
# Paste Fg on top of Bg, offset by (100,100)
Bg = ImageBuf("grid.exr")
Fg = ImageBuf("tahoe.tif")
ImageBufAlgo.paste(Bg, 100, 100, 0, 0, Fg)
```

oiiotool

```
# Paste fg.exr on top of bg.exr, offset by (100,100)
oiiotool bg.exr fg.exr --paste +100+100 -o bg.exr
```

group rotateN

Return (or copy into dst) a rotated copy of the image pixels of src, in 90 degree increments. Pictorially:

rotate90	rotate180	rotate270
-----	-----	-----
AB --> CA	AB --> DC	AB --> BD
CD DB	CD BA	CD AC

Functions

ImageBuf **rotate90**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

ImageBuf **rotate180**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

ImageBuf **rotate270**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **rotate90**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **rotate180**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **rotate270**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:

C++

```
ImageBuf A("grid.exr");
ImageBuf R90 = ImageBufAlgo::rotate90(A);
ImageBuf R180 = ImageBufAlgo::rotate180(A);
ImageBuf R270 = ImageBufAlgo::rotate270(A);
```

Python

```
A = ImageBuf("grid.exr")
R90 = ImageBufAlgo.rotate90(A)
R180 = ImageBufAlgo.rotate180(A)
R270 = ImageBufAlgo.rotate270(A)
```

oiiotool

```
oiiotool grid.jpg -rotate 90 -o R90.jpg
oiiotool grid.jpg -rotate 180 -o R180.jpg
oiiotool grid.jpg -rotate 270 -o R270.jpg
```

group **flip-flop-transpose**

Return (or copy into dst) a subregion of src, but with the scanlines exchanged vertically (flip), or columns exchanged horizontally (flop), or transposed across the diagonal by swapping rows for columns (transpose) within the display/full window. In other words,

flip	flop	transpose
-----	-----	-----

(continues on next page)

(continued from previous page)

AB	-->	CD	AB	-->	BA	AB	-->	AC
CD		AB	CD		DC	CD		BD

Functions

ImageBuf **flip**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

ImageBuf **flop**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

ImageBuf **transpose**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **flip**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **flop**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **transpose**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:

C++

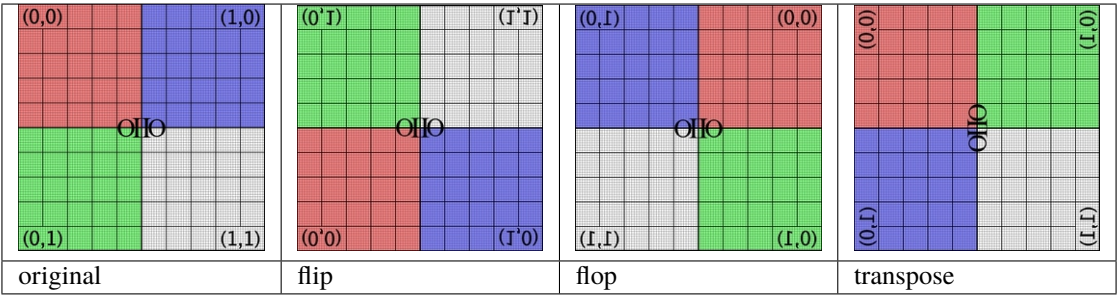

```
ImageBuf A("grid.exr");
ImageBuf B1 = ImageBufAlgo::flip(A);
ImageBuf B2 = ImageBufAlgo::flop(A);
ImageBuf B3 = ImageBufAlgo::transpose(A);
```

Python

```
A = ImageBuf("grid.exr")
B1 = ImageBufAlgo.flip(A)
B2 = ImageBufAlgo.flop(A)
B3 = ImageBufAlgo.transpose(A)
```

oiiotool

```
oiiotool grid.jpg --flip -o flip.jpg
oiiotool grid.jpg --flop -o flop.jpg
oiiotool grid.jpg --transpose -o transpose.jpg
```

ImageBuf OIIO::ImageBufAlgo::**reorient**(const ImageBuf &src, int nthreads = 0)

Return (or store into *dst*) a copy of *src*, but with whatever series of rotations, flips, or flops are necessary to transform the pixels into the configuration suggested by the “Orientation” metadata of the image (and the “Orientation” metadata is then set to 1, ordinary orientation).

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::reorient(ImageBuf &dst, const ImageBuf &src, int nthreads
                                  = 0)
```

Write to an existing image *dst* (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf A("grid-vertical.exr");
A = ImageBufAlgo::reorient(A);
```

Python

```
A = ImageBuf("grid-vertical.exr")
A = ImageBufAlgo.reorient(A)
```

oiitool

```
oiitool tahoe.jpg --reorient -o out.jpg
```

ImageBuf OIIO::ImageBufAlgo::**circular_shift**(const ImageBuf &src, int xshift, int yshift, int zshift = 0, *ROI* roi = {}, int nthreads = 0)

Return a subregion of *src*, but circularly shifting by the given amount. To clarify, the circular shift of [0,1,2,3,4,5] by +2 is [4,5,0,1,2,3].

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::circular_shift(ImageBuf &dst, const ImageBuf &src, int xshift, int
                                         yshift, int zshift = 0, ROI roi = {}, int nthreads = 0)
```

Write to an existing image *dst* (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf A("grid.exr");
ImageBuf B = ImageBufAlgo::circular_shift(A, 70, 30);
```

Python

```
A = ImageBuf("grid.exr")
B = ImageBufAlgo.circular_shift(A, 70, 30)
```

oiitool

```
oiiotool tahoe.jpg --cshift +70+30 -o out.jpg
```

group **rotate**

Rotate the `src` image by the `angle` (in radians, with positive angles clockwise). When `center_x` and `center_y` are supplied, they denote the center of rotation, in pixel coordinates; in their absence, the rotation will be about the center of the image's display window.

Only the pixels (and channels) of `dst` that are specified by `roi` will be copied from the rotated `src`; the default `roi` is to alter all the pixels in `dst`. If `dst` is uninitialized, it will be resized to be an `ImageBuf` large enough to hold the rotated image if `recompute_roi` is true, or will have the same *ROI* as `src` if `recompute_roi` is false. It is an error to pass both an uninitialized `dst` and an undefined `roi`.

The filter is used to weight the `src` pixels falling underneath it for each `dst` pixel. The caller may specify a reconstruction filter by name and width (expressed in pixels units of the `dst` image), or `rotate()` will choose a reasonable default high-quality default filter (lanczos3) if the empty string is passed, and a reasonable filter width if `filterwidth` is 0. (Note that some filter choices only make sense with particular width, in which case this `filterwidth` parameter may be ignored.)

Functions

```
ImageBuf rotate(const ImageBuf &src, float angle, string_view filtername = string_view(), float filterwidth = 0.0f, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)
```

```
ImageBuf rotate(const ImageBuf &src, float angle, Filter2D *filter, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)
```

```
ImageBuf rotate(const ImageBuf &src, float angle, float center_x, float center_y, string_view filtername = string_view(), float filterwidth = 0.0f, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)
```

```
ImageBuf rotate(const ImageBuf &src, float angle, float center_x, float center_y, Filter2D *filter, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)
```

```
bool rotate(ImageBuf &dst, const ImageBuf &src, float angle, string_view filtername = string_view(), float filterwidth = 0.0f, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)
```

```
bool rotate(ImageBuf &dst, const ImageBuf &src, float angle, Filter2D *filter, bool recompute_roi = false,
             ROI roi = {}, int nthreads = 0)
```

```
bool rotate(ImageBuf &dst, const ImageBuf &src, float angle, float center_x, float center_y, string_view
             filename = string_view(), float filterwidth = 0.0f, bool recompute_roi = false, ROI roi = {}, int
             nthreads = 0)
```

```
bool rotate(ImageBuf &dst, const ImageBuf &src, float angle, float center_x, float center_y, Filter2D *filter,
             bool recompute_roi = false, ROI roi = {}, int nthreads = 0)
```

Examples:

C++

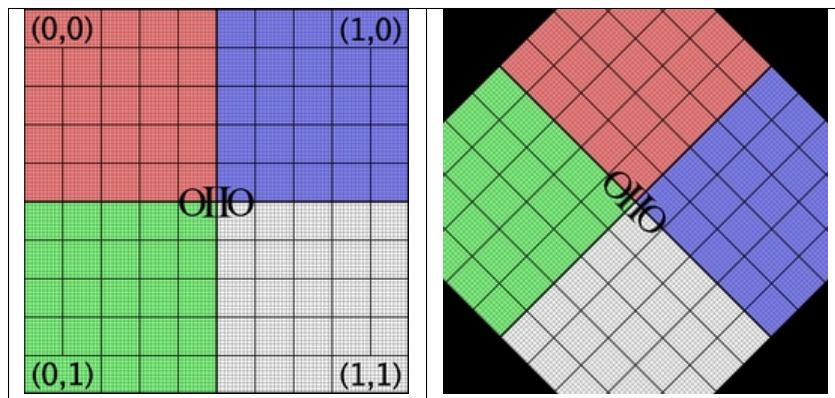

```
ImageBuf Src ("grid.exr");
ImageBuf Dst = ImageBufAlgo::rotate (Src, 45.0);
```

Python

```
Src = ImageBuf("grid.exr")
Dst = ImageBufAlgo.rotate(Src, 45.0)
```

oiitool

```
oiitool tahoe.exr --rotate 45.0 -o out.exr
```

group **resize**

Set `dst`, over the region of interest, to be a resized version of the corresponding portion of `src` (mapping such that the “full” image window of each correspond to each other, regardless of resolution). If `dst` is not yet initialized, it will be sized according to `roi`.

The `options` list contains optional `ParamValue`’s that control the resizing behavior. The following options are recognized:

- “filename” : string (default: “”)

The type of reconstruction filter used to weight the `src` pixels falling underneath it for each `dst` pixel. If the value is the empty string or not supplied, a reasonable high-quality filter will be chosen automatically (blackman-harris when upsizing, lanczos3 when downsizing).

- "filterwidth" : float (default: 0)

The width of the reconstruction filter, expressed in pixel units of the `dst` image. If 0 or not supplied, the default width of the named filter will be used.

- "filterptr" : pointer to a `Filter2D` (default: nullptr)

Advanced use: It is also possible to pass a custom reconstruction filter as a `Filter2D*`, overriding any filtername and filterwidth that may also be passed. The easiest way to pass it is as: `make_pvt("filterptr", raw_filter_ptr)`. Use with caution!

The caller may either (a) explicitly pass a reconstruction filter, or (b) specify one by filtername and filterwidth. If filter is nullptr or if filtername is the empty string `resize()` will choose a reasonable high-quality default (blackman-harris when upsizing, lanczos3 when downsizing). The filter is used to weight the `src` pixels falling underneath it for each `dst` pixel; the filter's size is expressed in pixel units of the `dst` image.

Functions

`ImageBuf` **resize**(const `ImageBuf` &src, `KWArgs` options = {}, `ROI` roi = {}, int nthreads = 0)

bool **resize**(`ImageBuf` &dst, const `ImageBuf` &src, `KWArgs` options = {}, `ROI` roi = {}, int nthreads = 0)

Examples:

C++

```
// Resize the image to 640x480, using the default filter
ImageBuf Src("grid.exr");
ROI roi(0, 320, 0, 240, 0, 1, /*chans:*/ 0, Src.nchannels());
ImageBuf Dst = ImageBufAlgo::resize(Src, {}, roi);
```

Python

```
# Resize the image to 640x480, using the default filter
Src = ImageBuf("grid.exr")
roi = ROI(0, 320, 0, 240, 0, 1, 0, Src.nchannels)
Dst = ImageBufAlgo.resize(Src, roi=roi)
```

oiitool

```
# Resize the image to 640x480, using the default filter
oiitool grid.exr --resize 640x480 -o out.exr
```

`ImageBuf` `OIIO::ImageBufAlgo::resample`(const `ImageBuf` &src, bool interpolate = true, *ROI* roi = {}, int nthreads = 0)

Set `dst`, over the region of interest, to be a resized version of the corresponding portion of `src` (mapping such that the "full" image window of each correspond to each other, regardless of resolution). If `dst` is not yet initialized, it will be sized according to `roi`.

Unlike `ImageBufAlgo::resize()`, `resample()` does not take a filter; it just samples either with a bilinear interpolation (if `interpolate` is `true`, the default) or uses the single “closest” pixel (if `interpolate` is `false`). This makes it a lot faster than a proper `resize()`, though obviously with lower quality (aliasing when downsizing, pixel replication when upsizing).

For “deep” images, this function returns copies the closest source pixel needed, rather than attempting to interpolate deep pixels (regardless of the value of `interpolate`).

See also:

`ImageBufAlgo::resize()`

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::resample(ImageBuf &dst, const ImageBuf &src, bool interpolate =
                                true, ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
// Resample quickly to 320x240, with default interpolation
ImageBuf Src("grid.exr");
ROI roi(0, 320, 0, 240, 0, 1, /*chans:*/ 0, Src.nchannels());
ImageBuf Dst = ImageBufAlgo::resample(Src, true, roi);
```

Python

```
# Resample quickly to 320x240, with default interpolation
Src = ImageBuf("grid.exr")
roi = ROI(0, 320, 0, 240, 0, 1, 0, Src.nchannels)
Dst = ImageBufAlgo.resample(Src, roi=roi)
```

oiiotool

```
# Resample quickly to 320x240, with default interpolation
oiiotool tahoe.exr --resample 320x240 -o out.exr
```

group **fit**

Resize `src` to fit into `dst` (to a size specified by `roi`, if `dst` is not initialized), preserving its original aspect ratio. Thus, it will resize to be the largest size with the same aspect ratio that can fit inside the region, but will not necessarily completely fill it in both dimensions if the source and destination image buffers do not have the same aspect ratio.

The `options` list contains optional `ParamValue`’s that control the resizing behavior. The following options are recognized:

- “filtername” : string (default: “”)

The type of reconstruction filter used to weight the `src` pixels falling underneath it for each `dst` pixel. If the value is the empty string or not supplied, a reasonable high-quality filter will be chosen automatically (blackman-harris when upsizing, lanczos3 when downsizing).

- `"filterwidth"` : float (default: 0)

The width of the reconstruction filter, expressed in pixel units of the `dst` image. If 0 or not supplied, the default width of the named filter will be used.

- `"filterptr"` : pointer to a `Filter2D` (default: `nullptr`)

Advanced use: It is also possible to pass a custom reconstruction filter as a `Filter2D*`, overriding any filtername and filterwidth that may also be passed. The easiest way to pass it is as: `make_pv("filterptr", raw_filter_ptr)`. Use with caution!

- `"fillmode"` : string (default: "letterbox")

The `fillmode` determines which of several methods will be used to determine how the image will fill the new frame, if its aspect ratio does not precisely match the original source aspect ratio:

- `"width"` exactly fills the width of the new frame, either cropping or letterboxing the height if it isn't precisely the right size to preserve the original aspect ratio.
- `"height"` exactly fills the height of the new frame, either cropping or letterboxing the width if it isn't precisely the right size to preserve the original aspect ratio.
- `"letterbox"` (the default) chooses whichever of `"width"` or `"height"` will maximally fill the new frame with no image data lost (it will only letterbox, never crop).

- `"exact"` : int (default: 0)

If nonzero, will result in an exact match on aspect ratio and centering (partial pixel shift if necessary), whereas `exact=false` will only preserve aspect ratio and centering to the precision of a whole pixel.

Functions

`ImageBuf` **fit**(const `ImageBuf` &`src`, `KWArgs` options = {}, `ROI` roi = {}, int nthreads = 0)

bool **fit**(`ImageBuf` &`dst`, const `ImageBuf` &`src`, `KWArgs` options = {}, `ROI` roi = {}, int nthreads = 0)

Examples:

C++

```
// Resize to fit into a max of 640x480, preserving the aspect ratio
ImageBuf Src("grid.exr");
ROI roi(0, 320, 0, 240, 0, 1, /*chans:*/ 0, Src.nchannels());
ImageBuf Dst = ImageBufAlgo::fit(Src, {}, roi);
```

Python

```
# Resize to fit into a max of 640x480, preserving the aspect ratio
Src = ImageBuf("grid.exr")
roi = ROI(0, 320, 0, 240, 0, 1, 0, Src.nchannels)
Dst = ImageBufAlgo.fit(Src, "", roi=roi)
```

oiitool

```
# Resize to fit into a max of 640x480, preserving the aspect ratio
oiitool grid.exr --fit 640x480 -o out.exr
```

group warp

Warp the `src` image using the supplied 3x3 transformation matrix.

Only the pixels (and channels) of `dst` that are specified by `roi` will be copied from the warped `src`; the default is to alter all the pixels in `dst`. If `dst` is uninitialized, it will be sized to be an `ImageBuf` large enough to hold the warped image if `recompute_roi` is true, or will have the same *ROI* as `src` if `recompute_roi` is false. It is an error to pass both an uninitialized `dst` and an undefined `roi`.

The `options` list contains optional `ParamValue`'s that may control the filtering and reconstruction. The following options are recognized:

- “`filtername`” : string (default: “”)

The type of reconstruction filter used to weight the `src` pixels falling underneath it for each `dst` pixel. If the value is the empty string or not supplied, a reasonable high-quality filter will be chosen automatically.

- “`filterwidth`” : float (default: 0)

The width of the reconstruction filter, expressed in pixel units of the `dst` image. If 0 or not supplied, the default width of the named filter will be used.

- “`wrap`” : string (default: “black”)

The wrap mode controlling the value of pixel lookups that need to occur beyond the boundary of the `src` image. (Could be one of: black, clamp, periodic, mirror.)

- “`edgeclamp`” : int (default: 0)

If nonzero, will enable special edge clamp behavior to reduce artifacts at the image edges (experimental).

- “`recompute_roi`” : int (default: 0)

If nonzero and `dst` is not yet initialized, the result image will be sized to be large enough to hold the warped image. If zero (the default), the `dst` image will have the same *ROI* as `src`. If the `dst` image already is initialized, its size will not be changed and this option will be ignored.

- “`filterptr`” : pointer to a `Filter2D` (default: `nullptr`)

Advanced use: It is also possible to pass a custom reconstruction filter as a `Filter2D*`, overriding any `filtername` and `filterwidth` that may also be passed. The easiest way to pass it is as: `make_pv(“filterptr”, raw_filter_ptr)`. Use with caution!

param dst

The output `ImageBuf`. If not already initialized, it will be sized based on `roi` (which itself will default to the size of `src`, if not specified).

param src

The source `ImageBuf`.

param M

A 3x3 matrix describing the desired spatial transformation of destination pixel coordinates to source pixel coordinates.

param roi

The region of `dst` that will receive transformed pixels. If not specified, it will be all the pixels of `dst`.

param options

Optional ParamValue's that may control the filtering and reconstruction.

Functions

ImageBuf **warp**(const ImageBuf &src, M33fParam M, KWArgs options = {}, ROI roi = {}, int nthreads = 0)

bool **warp**(ImageBuf &dst, const ImageBuf &src, M33fParam M, KWArgs options = {}, ROI roi = {}, int nthreads = 0)

Examples:

C++

```
Imath::M33f M( 0.7071068, 0.7071068, 0,
              -0.7071068, 0.7071068, 0,
               20,      -8.284271, 1);
ImageBuf Src("grid.exr");
ImageBuf Dst = ImageBufAlgo::warp(Src, M, { { "filtername", "lanczos3"
↪ } } );
```

Python

```
M = (0.7071068, 0.7071068, 0,
     -0.7071068, 0.7071068, 0,
      20,      -8.284271, 1)
Src = ImageBuf("grid.exr")
Dst = ImageBufAlgo.warp(Src, M, filtername="lanczos3")
```

oiiotool

```
oiiotool grid.exr --warp 0.7071068,0.7071068,0,-0.7071068,0.7071068,0,
↪ 20,-8.284271,1 -o out.exr
```

group **st_warp**

Warp the src image using “st” coordinates from a secondary stbuf image.

Each pixel in the stbuf image is used as a normalized image-space coordinate in the src image, which is then sampled at that position using the given reconstruction filter to produce an output pixel.

The transform is only defined over the area of the stbuf image, and thus the given roi argument will be intersected with its geometry.

NOTE: The current behavior of this transform is modeled to match Nuke's STMap node.

param dst

The output ImageBuf. If an initialized buffer is provided, its full-size dimensions must match those of stbuf.

param src

The source ImageBuf to warp.

param stbuf

The ImageBuf holding the st coordinates. This must be holding a floating-point pixel data type.

param chan_s

The index of the “s” channel in the stbuf image. This defaults to its first channel.

param chan_t

The index of the “t” channel in the stbuf image. This defaults to its second channel.

param flip_s

Whether to mirror the “s” coordinate along the horizontal axis when computing source pixel positions. This is useful if the coordinates are defined in terms of a different image origin than OpenImageIO’s.

param flip_t

Whether to mirror the “t” coordinate along the vertical axis when computing source pixel positions. This is useful if the coordinates are defined in terms of a different image origin than OpenImageIO’s.

Functions

```
ImageBuf st_warp(const ImageBuf &src, const ImageBuf &stbuf, string_view filtername = string_view(),
    float filterwidth = 0.0f, int chan_s = 0, int chan_t = 1, bool flip_s = false, bool flip_t =
    false, ROI roi = {}, int nthreads = 0)
```

```
ImageBuf st_warp(const ImageBuf &src, const ImageBuf &stbuf, const Filter2D *filter, int chan_s = 0, int
    chan_t = 1, bool flip_s = false, bool flip_t = false, ROI roi = {}, int nthreads = 0)
```

```
bool st_warp(ImageBuf &dst, const ImageBuf &src, const ImageBuf &stbuf, string_view filtername =
    string_view(), float filterwidth = 0.0f, int chan_s = 0, int chan_t = 1, bool flip_s = false, bool
    flip_t = false, ROI roi = {}, int nthreads = 0)
```

```
bool st_warp(ImageBuf &dst, const ImageBuf &src, const ImageBuf &stbuf, const Filter2D *filter, int chan_s
    = 0, int chan_t = 1, bool flip_s = false, bool flip_t = false, ROI roi = {}, int nthreads = 0)
```

```
ImageBuf OIIO::ImageBufAlgo::demosaic(const ImageBuf &src, Kwargs options = {}, ROI roi = {}, int
    nthreads = 0)
```

Performs demosaicing of a raw digital camera image. Expects the src to be a single channel image. Returns a three channel RGB image with the color channels reconstructed using the selected algorithm.

The options list contains optional ParamValue’s that may control the reconstruction. The following options are recognized:

- “pattern” : string (default: “bayer”)

The type of image sensor color filter array. Currently only the Bayer-pattern images are supported.

- “algorithm” : string (default: “linear”)

The demosaicing algorithm, pattern-specific. The following algorithms are supported for Bayer-pattern images:

- **linear** - simple bilinear demosaicing. Fast, but can produce artefacts along sharp edges.
- **MHC** - Malvar-He-Cutler linear demosaicing algorithm. Slower than **linear**, but produces significantly better results.
- **"layout"**: string (default: "RGGB")

The order the color filter array elements are arranged in, pattern-specific.

Parameters

options – Optional ParamValue's that may control the reconstruction.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::demosaic(ImageBuf &dst, const ImageBuf &src, KWArgs options = {},
                                   ROI roi = {}, int nthreads = 0)
```

Write to an existing image **dst** (allocating if it is uninitialized).

Examples:

C++

```
ImageSpec hint;
hint["raw:Demosaic"] = "none";
ImageBuf Src ("test.cr3", 0, 0, nullptr, &hint);
ParamValue options[] = { { "layout", "GRBG" } };
ImageBuf Dst = ImageBufAlgo::demosaic (Src, options);
```

Python

```
hint = ImageSpec()
hint["raw:Demosaic"] = "none"
Src = ImageBuf("test.cr3", 0, 0, hint)
Dst = OpenImageIO.ImageBufAlgo.demosaic(Src, layout="GRBG")
```

oiiotool

```
oiiotool -iconfig raw:Demosaic none -i test.cr3 --demosaic:layout=GRBG_
↪ -o out.exr
```

10.4 Image arithmetic

```
ImageBuf OIIO::ImageBufAlgo::add(Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)
```

Compute per-pixel sum $A + B$, returning the result image.

A and B may each either be an **ImageBuf&**, or a **cspan<float>** giving a per-channel constant, or a single constant used for all channels. (But at least one must be an image.)

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::add(ImageBuf &dst, Image_or_Const A, Image_or_Const B,
                              ROI roi = {}, int nthreads = 0)
```

Write to an existing image **dst** (allocating if it is uninitialized).

Examples:

C++

```
// Add images A and B
ImageBuf A ("A.exr");
ImageBuf B ("B.exr");
ImageBuf Sum = ImageBufAlgo::add(A, B);

// Add 0.2 to channels 0-2, but not to channel 3
ImageBuf SumCspan = ImageBufAlgo::add(A, { 0.2f, 0.2f, 0.2f, 0.0f });
```

Python

```
# Add images A and B
A = ImageBuf("A.exr")
B = ImageBuf("B.exr")
Sum = ImageBufAlgo.add (A, B)

# Add 0.2 to channels 0-2, but not to channel 3
Sum_cspan = ImageBufAlgo.add (A, (0.2, 0.2, 0.2, 0.0))
```

oiitool

```
# Add images A and B
oiitool a.exr b.exr --add -o sum.exr

# Add 0.2 to channels 0-2, but not to channel 3
oiitool a.exr --addc 0.2,0.2,0.2,0.0 -o sum.exr
```

`ImageBuf OIIO::ImageBufAlgo::sub(Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)`

Compute per-pixel signed difference $A - B$, returning the result image.

A and B may each either be an `ImageBuf&`, or a `cspan<float>` giving a per-channel constant, or a single constant used for all channels. (But at least one must be an image.)

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::sub(ImageBuf &dst, Image_or_Const A, Image_or_Const B,
                             ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf A ("A.exr");
ImageBuf B ("B.exr");
ImageBuf Diff = ImageBufAlgo::sub(A, B);
```

Python

```
A = ImageBuf("A.exr")
B = ImageBuf("B.exr")
Diff = ImageBufAlgo.sub (A, B)
```

oiiotool

```
oiiotool a.exr b.exr --sub -o diff.exr
```

ImageBuf OIIO::ImageBufAlgo::**absdiff**(Image_or_Const A, Image_or_Const B, *ROI* roi = {}, int nthreads = 0)

Compute per-pixel absolute difference $\text{abs}(A - B)$, returning the result image.

A and B may each either be an ImageBuf&, or a `cspan<float>` giving a per-channel constant, or a single constant used for all channels. (But at least one must be an image.)

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::absdiff(ImageBuf &dst, Image_or_Const A,
                                Image_or_Const B, ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf A ("A.exr");
ImageBuf B ("B.exr");
ImageBuf Diff = ImageBufAlgo::absdiff (A, B);
```

Python

```
A = ImageBuf("A.exr")
B = ImageBuf("B.exr")
Diff = ImageBufAlgo.absdiff (A, B)
```

oiiotool

```
oiiotool a.exr b.exr --absdiff -o diff.exr
```

ImageBuf OIIO::ImageBufAlgo::**abs**(const ImageBuf &A, *ROI* roi = {}, int nthreads = 0)

Compute per-pixel absolute value $\text{abs}(A)$, returning the result image.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::abs(ImageBuf &dst, const ImageBuf &A, ROI roi = {}, int
                             nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf A("grid.exr");  
ImageBuf Abs = ImageBufAlgo::abs(A);
```

Python

```
A = ImageBuf("grid.exr")  
Abs = ImageBufAlgo.abs (A)
```

oiitool

```
oiitool a.exr --abs -o abs.exr
```

`ImageBuf OIIO::ImageBufAlgo::mul`(Image_or_Const A, Image_or_Const B, *ROI* roi = {}, int nthreads = 0)

Compute per-pixel product $A * B$, returning the result image.

Either both A and B are images, or one is an image and the other is a `cspan<float>` giving a per-channel constant or a single constant used for all channels.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::mul(ImageBuf &dst, Image_or_Const A, Image_or_Const B,  
                             ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
// Pixel-by-pixel, channel-by-channel multiplication of A and B  
ImageBuf A ("A.exr");  
ImageBuf B ("B.exr");  
ImageBuf Product = ImageBufAlgo::mul (A, B);  
  
// In-place reduce intensity of A's channels 0-2 by 50%  
ImageBufAlgo::mul (A, A, { 0.5f, 0.5f, 0.5f, 1.0f });
```

Python

```
# Pixel-by-pixel, channel-by-channel multiplication of A and B  
A = ImageBuf("A.exr")  
B = ImageBuf("B.exr")  
Product = ImageBufAlgo.mul (A, B)  
  
# In-place reduce intensity of A's channels 0-2 by 50%  
ImageBufAlgo.mul (A, A, (0.5, 0.5, 0.5, 1.0))
```

oiitool

```
# Pixel-by-pixel, channel-by-channel multiplication of A and B
oiiotool a.exr b.exr --mul -o product.exr

# In-place reduce intensity of A's channels 0-2 by 50%
oiiotool a.exr --mulc 0.5,0.5,0.5,1.0 -o a.exr
```

ImageBuf OIIO::ImageBufAlgo::div(Image_or_Const A, Image_or_Const B, *ROI* roi = {}, int nthreads = 0)

Compute per-pixel division A / B , returning the result image. Division by zero is defined to result in zero.

A is always an image, and B is either an image or a `cspan<float>` giving a per-channel constant or a single constant used for all channels.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::div(ImageBuf &dst, Image_or_Const A, Image_or_Const B,
                             ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
// Pixel-by-pixel, channel-by-channel division of A by B
ImageBuf A ("A.exr");
ImageBuf B ("B.exr");
ImageBuf Ratio = ImageBufAlgo::div (A, B);

// In-place reduce intensity of A's channels 0-2 by 50%
ImageBufAlgo::div (A, A, { 2.0f, 2.0f, 2.0f, 1.0f });
```

Python

```
# Pixel-by-pixel, channel-by-channel division of A by B
A = ImageBuf("A.exr")
B = ImageBuf("B.exr")
Ratio = ImageBufAlgo.div (A, B)

# In-place reduce intensity of A's channels 0-2 by 50%
ImageBufAlgo.div (A, A, (2.0, 2.0, 2.0, 1.0))
```

oiiotool

```
# Pixel-by-pixel, channel-by-channel division of A by B
oiiotool a.exr b.exr --div -o ratio.exr

# In-place reduce intensity of A's channels 0-2 by 50%
oiiotool a.exr --divc 2,2,2,1 -o a.exr
```

ImageBuf OIIO::ImageBufAlgo::mad(Image_or_Const A, Image_or_Const B, Image_or_Const C, *ROI* roi = {}, int nthreads = 0)

Compute per-pixel multiply-and-add $A * B + C$, returning the result image.

A, B, and C are each either an image, or a `cspan<float>` giving a per-channel constant or a single constant used for all channels. (Note: at least one must be an image.)

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::mad(ImageBuf &dst, Image_or_Const A, Image_or_Const B,
                             Image_or_Const C, ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
// Pixel-by-pixel, channel-by-channel A * B + C
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf C ("c.exr");
ImageBuf Result = ImageBufAlgo::mad (A, B, C);

// Compute the "inverse" A, which is 1.0-A, as A*(-1) + 1
// Do this in-place, and only for the first 3 channels (leave any
// alpha channel, if present, as it is).
ImageBuf Ainv = ImageBufAlgo::mad (A, { -1.0, -1.0, -1.0, 1.0 },
                                   { 1.0, 1.0, 1.0, 0.0 });
```

Python

```
# Pixel-by-pixel, channel-by-channel A * B + C
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
C = ImageBuf("c.exr")
Result = ImageBufAlgo.mad (A, B, C)

# Compute the "inverse" A, which is 1.0-A, as A*(-1) + 1
# Do this in-place, and only for the first 3 channels (leave any
# alpha channel, if present, as it is).
Ainv = ImageBufAlgo.mad (A, (-1.0, -1.0, -1.0, 1.0), (1.0, 1.0, 1.0, 0.
↪0))
```

oiio tool

```
# Pixel-by-pixel, channel-by-channel A * B + C
oiio tool a.exr b.exr c.exr --mad -o result.exr
```

ImageBuf OIIO::ImageBufAlgo::over(const ImageBuf &A, const ImageBuf &B, *ROI* roi = {}, int nthreads = 0)

Return the composite of A over B using the Porter/Duff definition of “over”, returning true upon success and false for any of a variety of failures (as described below).

A and B (and dst, if already defined/allocated) must have valid alpha channels identified by their *ImageSpec* `alpha_channel` field. If A or B do not have alpha channels (as determined by those rules) or if the number of non-alpha channels do not match between A and B, `over()` will fail, returning false.

If dst is not already an initialized ImageBuf, it will be sized to encompass the minimal rectangular pixel region containing the union of the defined pixels of A and B, and with a number of channels equal to the number of non-alpha channels of A and B, plus an alpha channel. However, if dst is already initialized, it will not be resized, and the “over” operation will apply to its existing pixel data window. In this case, dst must have an alpha channel designated and must have the same number of non-alpha channels as A and B, otherwise it will fail, returning false.

A, B, and dst need not perfectly overlap in their pixel data windows; pixel values of A or B that are outside their respective pixel data window will be treated as having “zero” (0,0,0...) value.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::over(ImageBuf &dst, const ImageBuf &A, const ImageBuf
                               &B, ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf Composite = ImageBufAlgo::over (A, B);
```

C++

```
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
Composite = ImageBufAlgo.over (A, B)
```

oiiotool

```
oiiotool a.exr b.exr --over -o composite.exr
```

```
ImageBuf OIIO::ImageBufAlgo::zover(const ImageBuf &A, const ImageBuf &B, bool z_zeroisinf = false, ROI
                                     roi = {}, int nthreads = 0)
```

Just like `ImageBufAlgo::over()`, but inputs A and B must have designated ‘z’ channels, and on a pixel-by-pixel basis, the z values will determine which of A or B will be considered the foreground or background (lower z is foreground). If `z_zeroisinf` is true, then `z=0` values will be treated as if they are infinitely far away.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::zover(ImageBuf &dst, const ImageBuf &A, const ImageBuf
                                &B, bool z_zeroisinf = false, ROI roi = {}, int
                                nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf Composite = ImageBufAlgo::zover (A, B);
```

C++

```
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
Composite = ImageBufAlgo.zover (A, B)
```

oiiotool

```
oiiotool a.exr b.exr --zover -o composite.exr
```

`ImageBuf OIIO::ImageBufAlgo::invert`(const ImageBuf &A, *ROI* roi = {}, int nthreads = 0)

Compute per-pixel value inverse $1.0 - A$ (which you can think of as roughly meaning switching white and black), returning the result image.

Tips for callers: (1) You probably want to set `roi` to restrict the operation to only the color channels, and not accidentally include alpha, z, or others. (2) There may be situations where you want to `unpremult()` before the invert, then `premult()` the result, so that you are computing the inverse of the unmasked color.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::invert(ImageBuf &dst, const ImageBuf &A, ROI roi = {},
                                int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
// Invert all channels of A
ImageBuf A ("a.exr");
ImageBuf Inverse = ImageBufAlgo::invert (Inverse, A);

// In this example, we are careful to deal with alpha in an RGBA image.
// First we copy A to Inverse, un-premultiply the color values by
// ↪ alpha,
// invert just the color channels in-place, and then re-premultiply the
// colors by alpha.
roi = A.roi();
roi.chend = 3;      // Restrict roi to only R,G,B
ImageBuf Inverse = ImageBufAlgo::unpremult (A);
ImageBufAlgo::invert (Inverse, Inverse, roi);
ImageBufAlgo::repremult (Inverse, Inverse);
```

Python

```
# Invert all channels of A
A = ImageBuf("a.exr")
```

(continues on next page)

(continued from previous page)

```

Inverse = ImageBufAlgo.invert (Inverse, A)

# In this example, we are careful to deal with alpha in an RGBA image.
# First we copy A to Inverse, un-premultiply the color values by alpha,
# invert just the color channels in-place, and then re-premultiply the
# colors by alpha.
roi = A.roi.copy()
roi.chend = 3      # Restrict roi to only R,G,B
Inverse = ImageBufAlgo.unpremult (A)
ImageBufAlgo.invert (Inverse, Inverse, roi)
ImageBufAlgo.repremult (Inverse, Inverse)

```

oiiotool

```

# Invert all channels of A, including alpha.
# Because oiiotool --invert by default includes only the first
# 3 channels, we have to use optional modifiers to include alpha.
oiiotool a.exr --invert:chbegin=0:chend=3 -o inverse.exr

# In this example, invert only the RGB channels (which is the default
# behavior of oiiotool --invert) and also we un-premultiply the color
# values by alpha, invert, and then re-premultiply the colors by alpha.
oiiotool a.exr --unpremult --invert --repremult -o inverse.exr

```

ImageBuf OIIO::ImageBufAlgo::pow(const ImageBuf &A, *cspan*<float> B, *ROI* roi = {}, int nthreads = 0)

Compute per-pixel raise-to-power A^B . returning the result image. It is permitted for dst and A to be the same

image.

A is always an image, and B is either an image or a `cspan<float>` giving a per-channel constant or a single constant used for all channels.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::pow(ImageBuf &dst, const ImageBuf &A, cspan<float> B,  
                             ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
// Gamma-correct by 2.2 channels 0-2 of the image, in-place  
ImageBuf A ("a.exr");  
const float g = 1.0f / 2.2f;  
ImageBufAlgo::pow (A, A, { g, g, g, 1.0f });
```

Python

```
# Gamma-correct by 2.2 channels 0-2 of the image, in-place  
A = ImageBuf("a.exr")  
g = 1.0 / 2.2  
ImageBufAlgo.pow (A, A, (g, g, g, 1))
```

oiio tool

```
# Gamma-correct by 2.2 channels 0-2 of the image, in-place  
oiio tool a.exr --powc 0.4545,0.4545,0.4545,1.0 -o a.exr
```

`ImageBuf OIIO::ImageBufAlgo::channel_sum(const ImageBuf &src, cspan<float> weights = 1.0f, ROI roi = {}, int nthreads = 0)`

Converts a multi-channel image into a one-channel image via a weighted sum of channels:

```
(channel[0]*weight[0] + channel[1]*weight[1] + ...)
```

returning the resulting one-channel image. The `weights`, if not supplied, default to { 1, 1, 1, ... }.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::channel_sum(ImageBuf &dst, const ImageBuf &src,  
                                     cspan<float> weights = 1.0f, ROI roi = {}, int  
                                     nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

Compute luminance via a weighted sum of R,G,B (assuming Rec709 primaries and a linear scale):

C++

```
// Compute luminance via a weighted sum of R,G,B
// (assuming Rec709 primaries and a linear scale)
float luma_weights[3] = { .2126, .7152, .0722, 0.0 };
ImageBuf A ("a.exr");
ImageBuf lum = ImageBufAlgo::channel_sum (A, luma_weights);
```

Python

```
# Compute luminance via a weighted sum of R,G,B
# (assuming Rec709 primaries and a linear scale)
A = ImageBuf("a.exr")
lum = ImageBufAlgo.channel_sum (A, (.2126, .7152, .0722, 0.0))
```

oiiotool

```
# Compute luminance via a weighted sum of R,G,B
# (assuming Rec709 primaries and a linear scale)
oiiotool a.exr --chsum 0.2126,0.7152,0.0722,0.0 -o lum.exr
```

Max, min, clamp

group **maxminclamp**

max() and *min()* take the pixel-by-pixel, channel-by-channel maximum and minimum of two images, or of an image and a constant.

clamp() restricts values of an image to the range between per-channel minimum and maximum constant values.

Functions

ImageBuf **max**(Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Compute per-pixel *max*(A, B), returning the result image.

Either both A and B are images, or one is an image and the other is a *cspan<float>* giving a per-channel constant or a single constant used for all channels.

bool **max**(ImageBuf &dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Write to an existing image *dst* (allocating if it is uninitialized).

ImageBuf **min**(Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Compute per-pixel *min*(A, B), returning the result image.

Either both A and B are images, or one is an image and the other is a *cspan<float>* giving a per-channel constant or a single constant used for all channels.

bool **min**(ImageBuf &dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Write to an existing image *dst* (allocating if it is uninitialized).

ImageBuf **clamp**(const ImageBuf &src, *cspan<float>* min = -std::numeric_limits<float>::max(), *cspan<float>* max = std::numeric_limits<float>::max(), bool clampalpha01 = false, ROI roi = {}, int nthreads = 0)

Return pixels of `src` with pixel values clamped as follows:

Parameters

- **min** – The minimum clamp value for each channel. If `min` is empty, no minimum clamping is performed.
- **max** – The maximum clamp value for each channel. If `max` is empty, no maximum clamping is performed.
- **clampalpha01** – If true, then additionally any alpha channel is clamped to the 0-1 range.

bool **clamp**(ImageBuf &dst, const ImageBuf &src, *cspan*<float> min = -std::numeric_limits<float>::max(), *cspan*<float> max = std::numeric_limits<float>::max(), bool clampalpha01 = false, ROI roi = {}, int nthreads = 0)

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
// min of images A and B, assign to MinImage
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf MinImage = ImageBufAlgo::min (Sum, A, B);

// Squash negative values in A by taking max(A, 0.0) for all channels
ImageBuf A ("a.exr");
ImageBufAlgo::max (A, A, 0.0f);

// Clamp image buffer A in-place to the [0,1] range for all pixels.
ImageBufAlgo::clamp (A, A, 0.0f, 1.0f);

// Just clamp alpha to [0,1] in-place
ImageBufAlgo::clamp (A, A, -std::numeric_limits<float>::max(),
                    std::numeric_limits<float>::max(), true);

// Clamp R & G to [0,0.5], leave other channels alone
std::vector<float> min (A.nchannels(), -std::numeric_limits<float>
↳::max());
std::vector<float> max (A.nchannels(), std::numeric_limits<float>
↳::max());
min[0] = 0.0f; max[0] = 0.5f;
min[1] = 0.0f; max[1] = 0.5f;
ImageBufAlgo::clamp (A, A, &min[0], &max[0], false);
```

Python

```
# min of images A and B, assign to MinImage
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
MinImage = ImageBufAlgo.min (Sum, A, B)

# Squash negative values in A by taking max(A, 0.0) for all channels
A = ImageBuf("a.exr")
ImageBufAlgo.max (A, A, 0.0)
```

(continues on next page)

(continued from previous page)

```

# Clamp image buffer A in-place to the [0,1] range for all pixels.
ImageBufAlgo.clamp (A, A, 0.0, 1.0)

# Just clamp alpha to [0,1] in-place
ImageBufAlgo.clamp (A, A, -1.0e30, 1.0e30, True)

# Clamp R & G to [0,0.5], leave other channels alone
ImageBufAlgo.clamp (A, A, (0, 0, -1.0e30, -1.0e30),
                    (0.5, 0.5, 1.0e30, 1.0e30), False)

```

oiiotool

```

# min of images A and B, assign to MinImage
oiiotool a.exr b.exr --min -o minimage.exr

# Squash negative values in A by taking max(A, 0.0) for all channels
oiiotool.exr a.exr --maxc 0 -o a.exr

# Clamp image buffer A in-place to the [0,1] range for all pixels.
oiiotool.exr a.exr --clamp:min=0:max=1 -o a.exr

# Just clamp alpha to [0,1] in-place
oiiotool.exr a.exr --clamp:min=,,,0:max=,,,1 -o a.exr

# Clamp R & G to [0,0.5], leave other channels alone
oiiotool.exr a.exr --clamp:min=0,0,,,max=1,1,,, -o a.exr

```

group **maxminchan**

maxchan() computes a one-channel image that for each pixel, contains the maximum value of all channels of corresponding pixel of the source image. **minchan()** similarly computes the minimum value of all channels.

Version

2.3.10

Functions

ImageBuf **maxchan**(const ImageBuf &A, ROI roi = {}, int nthreads = 0)

bool **maxchan**(ImageBuf &dst, const ImageBuf &A, ROI roi = {}, int nthreads = 0)

ImageBuf **minchan**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **minchan**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:

C++

```
// Computes the maximum of R, G, B.
ImageBuf A ("rgb.exr");
ImageBuf B = ImageBufAlgo::maxchan (A);
```

Python

```
# Computes the maximum of R, G, B.
A = ImageBuf("a.exr")
B = ImageBufAlgo.maxchan (A)
```

oiiotool

```
# Computes the maximum of R, G, B.
oiiotool a.exr -maxchan -o b.exr
```

```
ImageBuf OIIO::ImageBufAlgo::contrast_remap(const ImageBuf &src, cspan<float> black = 0.0f,
                                             cspan<float> white = 1.0f, cspan<float> min = 0.0f,
                                             cspan<float> max = 1.0f, cspan<float> scontrast = 1.0f,
                                             cspan<float> sthresh = 0.5f, ROI = {}, int nthreads = 0)
```

Return pixel values that are a contrast-remap of the corresponding values of the `src` image, transforming pixel value domain [black, white] to range [min, max], either linearly or with optional application of a smooth sigmoidal remapping (if `scontrast != 1.0`).

The following steps are performed, in order:

- Linearly rescale values [black, white] to [0, 1].
- If `scontrast != 1`, apply a sigmoidal remapping where a larger `scontrast` value makes a steeper slope, and the steepest part is at value `sthresh` (relative to the new remapped value after steps 1 & 2; the default is 0.5).
- Rescale the range of that result: 0.0 -> min and 1.0 -> max.

Values outside of the [black,white] range will be extrapolated to outside [min,max], so it may be prudent to apply a `clamp()` to the results.

The black, white, min, max, scontrast, sthresh parameters may each either be a single float value for all channels, or a span giving per-channel values.

You can use this function for a simple linear contrast remapping of [black, white] to [min, max] if you use the default values for sthresh. Or just a simple sigmoidal contrast stretch within the [0,1] range if you leave all other parameters at their defaults, or a combination of these effects. Note that if `black == white`, the result will be a simple binary thresholding where values < black map to min and values >= black map to max.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::contrast_remap(ImageBuf &dst, const ImageBuf &src,
                                         cspan<float> black = 0.0f, cspan<float>
                                         white = 1.0f, cspan<float> min = 0.0f,
                                         cspan<float> max = 1.0f, cspan<float>
                                         scontrast = 1.0f, cspan<float> sthresh =
                                         0.5f, ROI = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf A ("tahoe.tif");

// Simple linear remap that stretches input 0.1 to black, and input
// 0.75 to white.
ImageBuf linstretch = ImageBufAlgo::contrast_remap (A, 0.1f, 0.75f);

// Remapping 0->1 and 1->0 inverts the colors of the image,
// equivalent to ImageBufAlgo::invert().
ImageBuf inverse = ImageBufAlgo::contrast_remap (A, 1.0f, 0.0f);

// Use a sigmoid curve to add contrast but without any hard cutoffs.
// Use a contrast parameter of 5.0.
ImageBuf sigmoid = ImageBufAlgo::contrast_remap (A, 0.0f, 1.0f,
                                                0.0f, 1.0f, 5.0f);
```

Python

```
A = ImageBuf("tahoe.tif")

# Simple linear remap that stretches input 0.1 to black, and input
# 0.75 to white.
linstretch = ImageBufAlgo.contrast_remap (A, 0.1, 0.75)

# Remapping 0->1 and 1->0 inverts the colors of the image,
# equivalent to ImageBufAlgo::invert().
inverse = ImageBufAlgo.contrast_remap (A, 1.0, 0.0)

# Use a sigmoid curve to add contrast but without any hard cutoffs.
# Use a contrast parameter of 5.0.
sigmoid = ImageBufAlgo.contrast_remap (A, 0.0, 1.0, 0.0, 1.0, 5.0)
```

oiiotool

```
# Simple linear remap that stretches input 0.1 to black, and input
# 0.75 to white.
oiiotool tahoe.exr --contrast:black=0.1:white=0.75 -o linstretch.exr

# Remapping 0->1 and 1->0 inverts the colors of the image,
# equivalent to ImageBufAlgo::invert().
oiiotool tahoe.tif --contrast:black=1.0:white=0.0:clamp=0 -o inverse.
↳tif

# Use a sigmoid curve to add contrast but without any hard cutoffs.
# Use a contrast parameter of 5.0.
oiiotool tahoe.tif --contrast:scontrast=5 -o sigmoid.tif
```

group **saturate**

Increase or decrease color saturation of the image.

The **saturate** operation returns (or copies into *dst*) the pixels of *src* within the *ROI*, and in the process adjusts the color saturation of the three consecutive channels starting with *firstchannel* based on the *scale* parameter: 0.0 fully desaturates to a greyscale image of perceptually equivalent luminance, 1.0 leaves the colors unchanged, scale values inside this range interpolate between them, and *scale* > 1 would increase apparent color saturation.

Channels that are within the range of *roi.chbegin* to *roi.chend*-1, but outside the range of *firstchannel* to *firstchannel*+2 are simply copied unaltered. Only three channels at a time can be desaturated, by default the first three channels, though *firstchannel* may be used to specify a different subset of channels. It is allowed for *src* and *dst* to be the same image.

Version

2.4+

Functions

`ImageBuf saturate(const ImageBuf &src, float scale = 0.0f, int firstchannel = 0, ROI roi = {}, int nthreads = 0)`

`bool saturate(ImageBuf &dst, const ImageBuf &src, float scale = 0.0f, int firstchannel = 0, ROI roi = {}, int nthreads = 0)`

Examples:

C++

```
ImageBuf img("tahoe.exr");
ImageBuf grey = ImageBufAlgo::saturate (img, 0.0f);
ImageBuf colorful = ImageBufAlgo::saturate (img, 2.0f);
```

Python

```
img = ImageBuf("tahoe.exr")
grey = ImageBufAlgo.saturate (img, 0.0)
colorful = ImageBufAlgo.saturate (img, 2.0)
```

oiiotool

```
oiiotool tahoe.exr -saturate 0.0 -o grey.exr
oiiotool tahoe.exr -saturate 2.0 -o colorful.exr
```

group **color_map**

Remap value range by spline or name

Return (or copy into `dst`) pixel values determined by looking up a color map using values of the source image, using either the channel specified by `srcchannel`, or the luminance of `src`'s RGB if `srcchannel` is -1. This happens for all pixels within the *ROI* (which defaults to all of `src`), and if `dst` is not already initialized, it will be initialized to the *ROI* and with color channels equal to `channels`.

In the variant that takes a `knots` parameter, this specifies the values of a linearly-interpolated color map given by `knots[nknots*channels]`. An input value of 0.0 is mapped to `knots[0..channels-1]` (one value for each color channel), and an input value of 1.0 is mapped to `knots[(nknots-1)*channels..knots.size()-1]`.

In the variant that takes a `mapname` parameter, this is the name of a color map. Recognized map names include: “inferno”, “viridis”, “magma”, “plasma”, all of which are perceptually uniform, strictly increasing in luminance, look good when converted to grayscale, and work for people with all types of colorblindness. Also “turbo” has most of these properties (except for being strictly increasing in luminance) and is a nice rainbow-like pattern. Also supported are the following color maps that do not have those desirable qualities (and are thus not recommended, but are present for back-compatibility or for use by clueless people): “blue-red”, “spectrum”, and “heat”. In all cases, the implied `channels` is 3.

Functions

ImageBuf **color_map**(const ImageBuf &src, int srcchannel, int nknots, int channels, *cspan*<float> knots, ROI roi = {}, int nthreads = 0)

ImageBuf **color_map**(const ImageBuf &src, int srcchannel, string_view mapname, ROI roi = {}, int nthreads = 0)

bool **color_map**(ImageBuf &dst, const ImageBuf &src, int srcchannel, int nknots, int channels, *cspan*<float> knots, ROI roi = {}, int nthreads = 0)

bool **color_map**(ImageBuf &dst, const ImageBuf &src, int srcchannel, string_view mapname, ROI roi = {}, int nthreads = 0)

Examples:

C++

```
// Use luminance of a.exr (assuming Rec709 primaries and a linear
// scale) and map to a spectrum-like palette:
ImageBuf A ("a.exr");
ImageBuf B = ImageBufAlgo::color_map (A, -1, "turbo");

// Use a custom color map
float mymap[] = { 0.25, 0.25, 0.25, 0, 0.5, 0, 1, 0, 0 };
B = ImageBufAlgo::color_map (A, -1 /* use luminance */,
                             3 /* num knots */, 3 /* channels */,
                             mymap);
```

Python

```
# Use luminance of a.exr (assuming Rec709 primaries and a linear
# scale) and map to a spectrum-like palette:
A = ImageBuf("a.exr")
B = ImageBufAlgo.color_map (A, -1, "turbo")

# Use a custom color map
B = ImageBufAlgo.color_map (A, -1, (0.25, 0.25, 0.25, 0, 0.5, 0, 1, 0, 0))
```

oiiotool

```
# Use luminance of a.exr (assuming Rec709 primaries and a linear
# scale) and map to a spectrum-like palette:
oiiotool a.exr --colormap turbo -o b.exr

# Use a custom color map
oiiotool a.exr --colormap turbo 0.25,0.25,0.25,0,0.5,0,1,0,0 -o b.exr
```

group **range**

Nonlinear range remapping for contrast preservation

[`rangecompress\(\)`](#) returns (or copy into `dst`) all pixels and color channels of `src` within region `roi` (defaulting to all the defined pixels of `dst`), rescaling their range with a logarithmic transformation. Alpha and z channels are not transformed.

[`rangeexpand\(\)`](#) performs the inverse transformation (logarithmic back into linear).

If `useluma` is true, the luma of channels [`roi.chbegin`..`roi.chbegin+2`] (presumed to be R, G, and B) are used to compute a single scale factor for all color channels, rather than scaling all channels individually (which could result in a color shift).

The purpose of these function is as follows: Some image operations (such as resizing with a “good” filter that contains negative lobes) can have objectionable artifacts when applied to images with very high-contrast regions involving extra bright pixels (such as highlights in HDR captured or rendered images). By compressing the range

pixel values, then performing the operation, then expanding the range of the result again, the result can be much more pleasing (even if not exactly correct).

Functions

ImageBuf **rangecompress**(const ImageBuf &src, bool useluma = false, ROI roi = {}, int nthreads = 0)

ImageBuf **rangeexpand**(const ImageBuf &src, bool useluma = false, ROI roi = {}, int nthreads = 0)

bool **rangecompress**(ImageBuf &dst, const ImageBuf &src, bool useluma = false, ROI roi = {}, int nthreads = 0)

bool **rangeexpand**(ImageBuf &dst, const ImageBuf &src, bool useluma = false, ROI roi = {}, int nthreads = 0)

Examples:

In this example, we resize the image to 640x480, using a Lanczos3 filter, which has negative lobes. To prevent those negative lobes from producing ringing or negative pixel values for HDR data, do range compression, then resize, then re-expand the range.

C++

```
// 1. Read the original image
ImageBuf Src ("tahoeHDR.exr");

// 2. Range compress to a logarithmic scale
ImageBuf Compressed = ImageBufAlgo::rangecompress (Src);

// 3. Now do the resize
ImageBuf Dst = ImageBufAlgo::resize (Compressed,
                                     { { "filtername", "lanczos3" }
                                       { "filterwidth", 6.0f } },
                                     ROI(0, 640, 0, 480));

// 4. Expand range to be linear again (operate in-place)
ImageBufAlgo::rangeexpand (Dst, Dst);
```

Python

```
# 1. Read the original image
Src = ImageBuf("tahoeHDR.exr")

# 2. Range compress to a logarithmic scale
Compressed = ImageBufAlgo.rangecompress (Src)

# 3. Now do the resize
Dst = ImageBufAlgo.resize (Compressed, filtername="lanczos3",
                           filterwidth=6.0, ROI(0, 640, 0, 480))

# 4. Expand range to be linear again (operate in-place)
ImageBufAlgo.rangeexpand (Dst, Dst)
```

oiiotool

```
oiiotool tahoeHDR.exr --rangecompress --resize 640x480 --rangeexpand -
-o out.exr

# Alternately, the --resize command has an option to do the
# range compression/expansion on its own:
oiiotool tahoeHDR.exr --resize:highlightcomp=1 640x480 -o out.exr
```

10.5 Image comparison and statistics

PixelStats OIIO::ImageBufAlgo::computePixelStats(const ImageBuf &src, *ROI* roi = {}, int nthreads = 0)

Compute statistics about the *ROI* of the src image, returning a PixelStats structure. Upon success, the returned vectors in the result structure will have size == src.nchannels(). If there is a failure, the vector sizes will be 0 and an error will be set in src.

The PixelStats structure is defined as follows in C++:

```
struct PixelStats {
    std::vector<float> min;
    std::vector<float> max;
    std::vector<float> avg;
    std::vector<float> stddev;
    std::vector<imagesize_t> nancount;
    std::vector<imagesize_t> infcount;
    std::vector<imagesize_t> finitecount;
};
```

Examples:

C++

```
ImageBuf A ("a.exr");
auto stats = ImageBufAlgo::computePixelStats(A);
if (stats.min.size() == 0)
    return; // empty vectors means we could not get the stats
for (int c = 0; c < A.nchannels(); ++c) {
    std::cout << "Channel " << c << ":\n";
    std::cout << "    min = " << stats.min[c] << "\n";
    std::cout << "    max = " << stats.max[c] << "\n";
    std::cout << "    average = " << stats.avg[c] << "\n";
    std::cout << "    standard deviation = " << stats.stddev[c] << "\n";
    std::cout << "    # NaN values = " << stats.nancount[c] << "\n";
    std::cout << "    # Inf values = " << stats.infcount[c] << "\n";
    std::cout << "    # finite values = " << stats.finitecount[c] << "\n";
}
```

Python

```

A = ImageBuf("a.exr")
stats = ImageBufAlgo.computePixelStats(A)
if stats is None :
    return
for c in A.channels :
    print ("Channel", c, ":")
    print ("  min =", stats.min[c])
    print ("  max =", stats.max[c])
    print ("  average =", stats.avg[c])
    print ("  standard deviation =", stats.stddev[c])
    print ("  # NaN values    =", stats.nancount[c])
    print ("  # Inf values     =", stats.infcount[c])
    print ("  # finite values  =", stats.finitecount[c])

```

oiiotool

```
oiiotool -stats -v a.exr
```

CompareResults OIIO::ImageBufAlgo::compare(const ImageBuf &A, const ImageBuf &B, float failthresh, float warnthresh, *ROI* roi = {}, int nthreads = 0)

Numerically compare two images. The difference threshold (for any individual color channel in any pixel) for a “failure” is failthresh, and for a “warning” is warnthresh. The results are stored in result. If roi is defined, pixels will be compared for the pixel and channel range that is specified. If roi is not defined, the comparison will be for all channels, on the union of the defined pixel windows of the two images (for either image, undefined pixels will be assumed to be black).

The CompareResults structure is defined in C++ as follows:

```

struct CompareResults {
    double meanerror, rms_error, PSNR, maxerror;
    int maxx, maxy, maxz, maxc;
    imagesize_t nwarn, nfail;
    bool error;
};

```

Examples:

C++

```

ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
auto comp = ImageBufAlgo::compare(A, B, 1.0f/255.0f, 0.0f);
if (comp.nwarn == 0 && comp.nfail == 0) {
    std::cout << "Images match within tolerance\n";
} else {
    std::cout << "Image differed: " << comp.nfail << " failures, "
               << comp.nwarn << " warnings.\n";
    std::cout << "Average error was " << comp.meanerror << "\n";
    std::cout << "RMS error was " << comp.rms_error << "\n";
}

```

(continues on next page)

(continued from previous page)

```

std::cout << "PSNR was " << comp.PSNR << "\n";
std::cout << "largest error was " << comp.maxerror
    << " on pixel (" << comp.maxx << "," << comp.maxy
    << "," << comp.maxz << "), channel " << comp.maxc << "\n";
}

```

Python

```

A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
comp = ImageBufAlgo.compare(A, B, 1.0f/255.0f, 0.0f)
if comp.nwarn == 0 and comp.nfail == 0 :
    print("Images match within tolerance")
else :
    print("Image differed:", comp.nfail, "failures,", comp.nwarn, "warnings.")
    print("Average error was", comp.meanerror)
    print("RMS error was", comp.rms_error)
    print("PSNR was", comp.PSNR)
    print("largest error was", comp.maxerror, "on pixel (",
        comp.maxx, ",", comp.maxy, ",", comp.maxz, "), channel", comp.maxc)

```

oiiotool

```
oiiotool a.exr b.exr --diff
```

```
int OIIO::ImageBufAlgo::compare_Yee(const ImageBuf &A, const ImageBuf &B, CompareResults &result,
    float luminance = 100, float fov = 45, ROI roi = {}, int nthreads = 0)
```

Compare two images using Hector Yee's perceptual metric, returning the number of pixels that fail the comparison. Only the first three channels (or first three channels specified by *roi*) are compared. Free parameters are the ambient luminance in the room and the field of view of the image display; our defaults are probably reasonable guesses for an office environment. The 'result' structure will store the maxerror, and the maxx, maxy, maxz of the pixel that failed most severely. (The other fields of the CompareResults are not used for Yee comparison.)

Works for all pixel types. But it's basically meaningless if the first three channels aren't RGB in a linear color space that sort of resembles AdobeRGB.

Return true on success, false on error.

```
bool OIIO::ImageBufAlgo::isConstantColor(const ImageBuf &src, float threshold = 0.0f, span<float> color =
    {}, ROI roi = {}, int nthreads = 0)
```

Do all pixels within the *ROI* have the same values for channels [*roi.chbegin*..*roi.chend*-1], within a tolerance of +/- threshold? If so, return true and store that color in color[*chbegin*..*chend*-1] (if color is not empty); otherwise return false. If *roi* is not defined (the default), it will be understood to be all of the defined pixels and channels of source.

Examples:

C++

```
ImageBuf A ("a.exr");
std::vector<float> color (A.nchannels());
if (ImageBufAlgo::isConstantColor (A, color)) {
    std::cout << "The image has the same value in all pixels: ";
    for (int c = 0; c < A.nchannels(); ++c)
        std::cout << (c ? " " : "") << color[c];
    std::cout << "\n";
} else {
    std::cout << "The image is not a solid color.\n";
}
```

Python

```
A = ImageBuf ("a.exr")
color = ImageBufAlgo.isConstantColor (A, color)
if color is not None :
    print ("The image has the same value in all pixels: ", color)
else :
    print ("The image is not a solid color.")
```

bool OIIO::ImageBufAlgo::isConstantChannel(const ImageBuf &src, int channel, float val, float threshold = 0.0f, ROI roi = {}, int nthreads = 0)

Does the requested channel have a given value (within a tolerance of +/- threshold) for every channel within the ROI? (For this function, the ROI's chbegin/chend are ignored.) Return true if so, otherwise return false. If roi is not defined (the default), it will be understood to be all of the defined pixels and channels of source.

Examples:

C++

```
ImageBuf A ("a.exr");
int alpha = A.spec().alpha_channel;
if (alpha < 0)
    std::cout << "The image does not have an alpha channel\n";
else if (ImageBufAlgo::isConstantChannel (A, alpha, 1.0f))
    std::cout << "The image has alpha = 1.0 everywhere\n";
else
    std::cout << "The image has alpha != 1 in at least one pixel\n";
```

Python

```
A = ImageBuf ("a.exr")
alpha = A.spec.alpha_channel
if alpha < 0 :
    print ("The image does not have an alpha channel")
else if ImageBufAlgo.isConstantChannel (A, alpha, 1.0f) :
    print ("The image has alpha = 1.0 everywhere")
```

(continues on next page)

(continued from previous page)

```
else
    print ("The image has alpha != 1 in at least one pixel")
```

```
bool OIIO::ImageBufAlgo::isMonochrome(const ImageBuf &src, float threshold = 0.0f, ROI roi = {}, int
                                     nthreads = 0)
```

Is the image monochrome within the *ROI*, i.e., for every pixel within the region, do all channels [roi.chbegin, roi.chend) have the same value (within a tolerance of +/- threshold)? If roi is not defined (the default), it will be understood to be all of the defined pixels and channels of source.

Examples:

C++

```
ImageBuf A ("a.exr");
ROI roi = get_roi (A.spec());
roi.chend = std::min (3, roi.chend); // only test RGB, not alpha
if (ImageBufAlgo::isMonochrome (A, roi))
    std::cout << "a.exr is really grayscale\n";
```

Python

```
A = ImageBuf("a.exr")
roi = A.roi.copy()
roi.chend = min(3, roi.chend)
if ImageBufAlgo.isMonochrome(A, roi) :
    print("a.exr is really grayscale")
```

```
bool OIIO::ImageBufAlgo::color_count(const ImageBuf &src, imagesize_t *count, int ncolors, cspan<float>
                                     color, cspan<float> eps = 0.001f, ROI roi = {}, int nthreads = 0)
```

Count how many pixels in the *ROI* match a list of colors. The colors to match are in:

```
colors[0 ... nchans-1]
colors[nchans ... 2*nchans-1]
...
colors[(ncolors-1)*nchans ... (ncolors*nchans)-1]
```

and so on, a total of ncolors consecutively stored colors of nchans channels each (nchans is the number of channels in the image, itself, it is not passed as a parameter).

eps[0..nchans-1] are the error tolerances for a match, for each channel. Setting eps[c] = numeric_limits<float>::max() will effectively make it ignore the channel. The default eps is 0.001 for all channels (this value is chosen because it requires exact matches for 8 bit images, but allows a wee bit of imprecision for float images).

Upon success, return true and store the number of pixels that matched each color count[0..ncolors-1]. If there is an error, returns false and sets an appropriate error message set in src.

Examples:

C++

```
ImageBuf A ("a.exr");
int n = A.nchannels();

// Try to match two colors: pure red and green
std::vector<float> colors (2*n, numeric_limits<float>::max());
colors[0] = 1.0f; colors[1] = 0.0f; colors[2] = 0.0f;
colors[n+0] = 0.0f; colors[n+1] = 1.0f; colors[n+2] = 0.0f;

const int ncolors = 2;
imagesize_t count[ncolors];
ImageBufAlgo::color_count (A, count, ncolors);
std::cout << "Number of red pixels   : " << count[0] << "\n";
std::cout << "Number of green pixels : " << count[1] << "\n";
```

oiiotool

```
oiiotool a.exr --colorcount "1,0,0;0,1,0"
```

bool OIIO::ImageBufAlgo::color_range_check(const ImageBuf &src, imagesize_t *lowcount, imagesize_t *highcount, imagesize_t *inrangecount, *cspan*<float> low, *cspan*<float> high, *ROI* roi = {}, int nthreads = 0)

Count how many pixels in the image (within the *ROI*) are outside the value range described by low[roi.chbegin..roi.chend-1] and high[roi.chbegin..roi.chend-1] as the low and high acceptable values for each color channel.

The number of pixels containing values that fall below the lower bound will be stored in *lowcount, the number of pixels containing values that fall above the upper bound will be stored in *highcount, and the number of pixels for which all channels fell within the bounds will be stored in *inrangecount. Any of these may be NULL, which simply means that the counts need not be collected or stored.

C++

```
ImageBuf A ("a.exr");
ROI roi = get_roi (A.spec());
roi.chend = std::min (roi.chend, 4); // only compare RGBA

float low[] = {0, 0, 0, 0};
float high[] = {1, 1, 1, 1};

imagesize_t lowcount, highcount, inrangecount;
ImageBufAlgo::color_range_check (A, &lowcount, &highcount, &inrangecount,
                                low, high, roi);
std::cout << lowcount << " pixels had components < 0\n";
std::cout << highcount << " pixels had components > 1\n";
std::cout << inrangecount << " pixels were fully within [0,1] range\n";
```

Python

```
A = ImageBuf("a.exr")
roi = A.roi.copy()
roi.chend = min (roi.chend, 4) # only compare RGBA

low = (0, 0, 0, 0)
high = (1, 1, 1, 1)

lowcount, highcount, inrangecount = ImageBufAlgo.color_range_check (A, low,
↪high, roi)
print(lowcount, "pixels had components < 0")
print(highcount, "pixels had components > 1")
print(inrangecount, "pixels were fully within [0,1] range")
```

oiiotool

```
oiiotool a.exr --rangecheck "0,0,0,0;1,1,1,1"
```

ROI `OIIO::ImageBufAlgo::nonzero_region`(const ImageBuf &src, *ROI* roi = {}, int nthreads = 0)

Find the minimal rectangular region within *roi* (which defaults to the entire pixel data window of *src*) that consists of nonzero pixel values. In other words, gives the region that is a “shrink-wraps” of *src* to exclude black border pixels. Note that if the entire image was black, the *ROI* returned will contain no pixels.

For “deep” images, this function returns the smallest *ROI* that contains all pixels that contain depth samples, and excludes the border pixels that contain no depth samples at all.

Examples:

C++

```
ImageBuf A ("a.exr");
ROI shrunk = ImageBufAlgo::nonzero_region (A);
if (shrunk.undefined())
    std::cout << "All pixels were empty\n";
else
    std::cout << "Non-empty region was " << shrunk << "\n";
```

Python

```
A = ImageBuf("a.exr")
shrunk = ImageBufAlgo.nonzero_region (A)
if not shrunk.defined :
    print ("All pixels were empty")
else :
    print ("Non-empty region was", shrunk)
```

```
std::string OIIO::ImageBufAlgo::computePixelHashSHA1(const ImageBuf &src, string_view extrainfo = "",
                                                    ROI roi = {}, int blocksize = 0, int nthreads = 0)
```

Compute the SHA-1 byte hash for all the pixels in the specified region of the image. If `blocksize > 0`, the function will compute separate SHA-1 hashes of each `blocksize` batch of scanlines, then return a hash of the individual hashes. This is just as strong a hash, but will NOT match a single hash of the entire image (`blocksize==0`). But by breaking up the hash into independent blocks, we can parallelize across multiple threads, given by `nthreads` (if `nthreads` is 0, it will use the global OIIO thread count). The `extrainfo` provides additional text that will be incorporated into the hash.

Examples:

C++

```
ImageBuf A ("a.exr");
std::string hash;
hash = ImageBufAlgo::computePixelHashSHA1 (A, "", ROI::All(), 64);
```

Python

```
A = ImageBuf("a.exr")
hash = ImageBufAlgo.computePixelHashSHA1 (A, blocksize=64)
```

```
std::vector<imagesize_t> OIIO::ImageBufAlgo::histogram(const ImageBuf &src, int channel = 0, int bins =
                                                    256, float min = 0.0f, float max = 1.0f, bool
                                                    ignore_empty = false, ROI roi = {}, int nthreads =
                                                    0)
```

Compute a histogram of `src`, for the given channel and `ROI`. Return a vector of length `bins` that contains the counts of how many pixel values were in each of `bins` equally spaced bins covering the range of values `[min, max]`. Values `< min` count for bin 0, values `> max` count for bin `nbins-1`. If `ignore_empty` is `true`, no counts will be incremented for any pixels whose value is 0 in all channels.

If there was an error, the returned vector will be empty, and an error message will be retrievable from `src.geterror()`.

Examples:

C++

```
ImageBuf Src ("tahoe.exr");
const int bins = 4;
auto hist = ImageBufAlgo::histogram (Src, 0, bins, 0.0f, 1.0f);
std::cout << "Channel 0 of the image had:\n";
float binsize = (max-min)/nbins;
for (int i = 0; i < nbins; ++i)
    hist[i] << " pixels that are >= " << (min+i*binsize) << " and "
        << (i == nbins-1 ? " <= " : " < ")
        << (min+(i+1)*binsize) << "\n";
```

Python

```

Src = ImageBuf("tahoe.exr")
bins = 4
hist = ImageBufAlgo.histogram (Src, channel=0, bins=4, min=0.0, max=1.0)
print ("Channel 0 of the image had:")
binsize = (max-min)/nbins
for i in range(nbins) :
    print (hist[i], "pixels that are >=", (min+i*binsize), "and",
           ("<=" if i == nbins-1 else "<"), (min+(i+1)*binsize))

```

10.6 Convolutions and frequency-space algorithms

ImageBuf OIIO::ImageBufAlgo::**make_kernel**(string_view name, float width, float height, float depth = 1.0f, bool normalize = true)

Make a 1-channel float image of the named kernel. The size of the image will be big enough to contain the kernel given its size (width x height) and rounded up to odd resolution so that the center of the kernel can be at the center of the middle pixel. If width and height are 0, the natural size of the named filter will be chosen. The kernel image will be offset so that its center is at the (0,0) coordinate. If **normalize** is true, the values will be normalized so that they sum to 1.0. If **depth** > 1, a volumetric kernel will be created. Use with caution!

Kernel names can be: “gaussian”, “sharp-gaussian”, “box”, “triangle”, “blackman-harris”, “mitchell”, “b-spline”, “catmull-rom”, “lanczos3”, “disk”, “binomial”, “laplacian”.

Note that “catmull-rom” and “lanczos3” are fixed-size kernels that don’t scale with the width, and are therefore probably less useful in most cases.

The ImageBuf that is returned indicates if there was an error, in which case `return.has_error()` will be true and `return.geterror()` can be used to retrieve an error message.

Examples:

C++

```
ImageBuf K = ImageBufAlgo::make_kernel ("gaussian", 5.0f, 5.0f);
```

Python

```
K = ImageBufAlgo.make_kernel ("gaussian", 5.0, 5.0)
```

oiio tool

```
oiio tool --makekernel gaussian 5x5 -o kernel.exr
```

ImageBuf OIIO::ImageBufAlgo::**convolve**(const ImageBuf &src, const ImageBuf &kernel, bool normalize = true, ROI roi = {}, int nthreads = 0)

Return the convolution of **src** and a **kernel**. If **roi** is not defined, it defaults to the full size **src**. If **normalized** is true, the kernel will be normalized for the convolution, otherwise the original values will be used.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::convolve(ImageBuf &dst, const ImageBuf &src, const
                                   ImageBuf &kernel, bool normalize = true, ROI roi
                                   = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized). If `roi` is not defined, it defaults to the full size of `dst` (or `src`, if `dst` was uninitialized). If `dst` is uninitialized, it will be allocated to be the size specified by `roi`.

Examples:

C++

```
// Blur an image with a 5x5 Gaussian kernel
ImageBuf Src ("tahoe.exr");
ImageBuf K = ImageBufAlgo::make_kernel ("gaussian", 5.0f, 5.0f);
ImageBuf Blurred = ImageBufAlgo::convolve (Src, K);
```

Python

```
Src = ImageBuf("tahoe.exr")
K = ImageBufAlgo.make_kernel ("gaussian", 5.0, 5.0)
Blurred = ImageBufAlgo.convolve (Src, K)
```

oiiotool

```
oiiotool tahoe.exr --makekernel gaussian 5x5 --convolve -o blurred.exr
```

```
ImageBuf OIIO::ImageBufAlgo::laplacian(const ImageBuf &src, ROI roi = {}, int nthreads = 0)
```

Return the Laplacian of the corresponding region of `src`. The Laplacian is the generalized second derivative of the image

$$\frac{\partial^2 s}{\partial x^2} + \frac{\partial^2 s}{\partial y^2}$$

which is approximated by convolving the image with a discrete 3x3 Laplacian kernel,

```
[ 0  1  0 ]
[ 1 -4  1 ]
[ 0  1  0 ]
```

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::laplacian(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
```

Write to an existing image *dst* (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf src ("tahoe.exr");
ImageBuf lap = ImageBufAlgo::laplacian (src);
```

Python

```
src = ImageBuf("tahoe.exr")
lap = ImageBufAlgo.laplacian (src)
```

oiiotool

```
oiiotool tahoe.exr --laplacian -o laplacian.exr
```

group **fft-iff**

Fast Fourier Transform and inverse

Return (or copy into *dst*) the discrete Fourier transform (DFT), or its inverse, of the section of *src* denoted by *roi*. If *roi* is not defined, it will be all of *src*'s pixels.

fft() takes the discrete Fourier transform (DFT) of the section of *src* denoted by *roi*, returning it or storing it in *dst*. If *roi* is not defined, it will be all of *src*'s pixels. Only one channel of *src* may be transformed at a time, so it will be the first channel described by *roi* (or, again, channel 0 if *roi* is undefined). If not already in the correct format, *dst* will be re-allocated to be a 2-channel float buffer of size *roi.width()* x *roi.height*, with channel 0 being the “real” part and channel 1 being the the “imaginary” part. The values returned are actually the unitary DFT, meaning that it is scaled by $1/\sqrt{\text{npixels}}$.

iff() takes the inverse discrete Fourier transform, transforming a 2-channel complex (real and imaginary) frequency domain image and into a single-channel spatial domain image. *src* must be a 2-channel float image, and is assumed to be a complex frequency-domain signal with the “real” component in channel 0 and the “imaginary” component in channel 1. *dst* will end up being a float image of one channel (the real component is kept, the imaginary component of the spatial-domain will be discarded). Just as with *fft()*, the *iff()* function is dealing with the unitary DFT, so it is scaled by $1/\sqrt{\text{npixels}}$.

Functions

ImageBuf **fft**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

ImageBuf **ifft**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **fft**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **ifft**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:

C++

```
ImageBuf Src ("tahoe.exr");

// Take the DFT of the first channel of Src
ImageBuf Freq = ImageBufAlgo::fft (Src);

// At this point, Freq is a 2-channel float image (real, imag)
// Convert it back from frequency domain to a spatial image
ImageBuf Spatial = ImageBufAlgo::ifft (Freq);
```

Python

```
src = ImageBuf("tahoe.exr")

# Take the DFT of the first channel of Src
Freq = ImageBufAlgo.fft (Src)

# At this point, Freq is a 2-channel float image (real, imag)
# Convert it back from frequency domain to a spatial image
Spatial = ImageBufAlgo.ifft (Freq)
```

oiiotool

```
oiiotool tahoe.exr --fft -o freq.exr
oiiotool freq.exr --ifft -o spatial.exr
```

group **complex-polar**

Converting complex to polar and back

The `polar_to_complex()` function transforms a 2-channel image whose channels are interpreted as complex values (real and imaginary components) into the equivalent values expressed in polar form of amplitude and phase (with phase between 0 and 2π).

The `complex_to_polar()` function performs the reverse transformation, converting from polar values (amplitude and phase) to complex (real and imaginary).

In either case, the section of `src` denoted by `roi` is transformed, storing the result in `dst`. If `roi` is not defined, it will be all of `src`'s pixels. Only the first two channels of `src` will be transformed.

The transformation between the two representations are:

```
real = amplitude * cos(phase);
imag = amplitude * sin(phase);

amplitude = hypot (real, imag);
phase = atan2 (imag, real);
```

Functions

ImageBuf **complex_to_polar**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **complex_to_polar**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

ImageBuf **polar_to_complex**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **polar_to_complex**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:

C++

```
// Suppose we have an FFT in frequency space values expressed as
// complex values (real, imaginary)
ImageBuf fft ("fft.exr");

// Convert to polar values (amplitude, phase)
ImageBuf Polar = ImageBufAlgo::complex_to_polar (fft);

// Convert from polar back to (real, imag)
ImageBuf Freq = ImageBufAlgo::polar_to_complex (Polar);
```

Python

```
# Suppose we have an FFT in frequency space values expressed as
# complex values (real, imaginary)
fft = ImageBuf("fft.exr")

# Convert to polar values (amplitude, phase)
Polar = ImageBufAlgo.complex_to_polar (fft)

# Convert from polar back to (real, imag)
Freq = ImageBufAlgo.polar_to_complex (Polar)
```

oiiotool

```
# Suppose we have an FFT in frequency space values expressed as
# complex values (real, imaginary).
# Convert to polar values (amplitude, phase)
oiiotool fft.exr --polar -o polar.exr

# Convert from polar back to (real, imag)
oiiotool polar.exr --unpolar -o freq.exr
```

10.7 Image Enhancement / Restoration

ImageBuf OIIO::ImageBufAlgo::**fixNonFinite**(const ImageBuf &src, NonFiniteFixMode mode = NONFINITE_BOX3, int *pixelsFixed = nullptr, *ROI* roi = {}, int nthreads = 0)

fixNonFinite() returns in image containing the values of *src* (within the *ROI*), while repairing any non-finite (NaN/Inf) pixels. If *pixelsFixed* is not nullptr, store in it the number of pixels that contained non-finite value. It is permissible to operate in-place (with *src* and *dst* referring to the same image).

How the non-finite values are repaired is specified by one of the mode parameter, which is an enum of NonFiniteFixMode.

This function works on all pixel data types, though it's just a copy for images with pixel data types that cannot represent NaN or Inf values.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::fixNonFinite(ImageBuf &dst, const ImageBuf &src,
                                     NonFiniteFixMode mode = NONFINITE_BOX3,
                                     int *pixelsFixed = nullptr, ROI roi = {}, int
                                     nthreads = 0)
```

Write to an existing image *dst* (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Src ("tahoe.exr");
int pixelsFixed = 0;
ImageBufAlgo::fixNonFinite (Src, Src, ImageBufAlgo::NONFINITE_BOX3,
                           &pixelsFixed);
std::cout << "Repaired " << pixelsFixed << " non-finite pixels\n";
```

Python

```
Src = ImageBuf("tahoe.exr")
ImageBufAlgo.fixNonFinite (Src, Src, "box3", oiio.NONFINITE_BOX3)
```

oiio tool

```
oiio tool tahoe.exr --fixnan box3 -o fixed.exr
```

ImageBuf OIIO::ImageBufAlgo::**fillholes_pushpull**(const ImageBuf &src, *ROI* roi = {}, int nthreads = 0)

Copy the specified *ROI* of *src* and fill any holes (pixels where alpha < 1) with plausible values using a push-pull technique. The *src* image must have an alpha channel. The *dst* image will end up with a copy of *src*, but will have an alpha of 1.0 everywhere within *roi*, and any place where the alpha of *src* was < 1, *dst* will have a pixel color that is a plausible “filling” of the original alpha hole.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::fillholes_pushpull(ImageBuf &dst, const ImageBuf &src,  
ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Src ("holes.exr");  
ImageBuf Filled = ImageBufAlgo::fillholes_pushpull (Src);
```

Python

```
Src = ImageBuf("holes.exr")  
Filled = ImageBufAlgo.fillholes_pushpull (Src)
```

oiitool

```
oiitool holes.exr --fillholes -o filled.exr
```

```
ImageBuf OIIO::ImageBufAlgo::median_filter(const ImageBuf &src, int width = 3, int height = -1, ROI roi =  
{}, int nthreads = 0)
```

Return a median-filtered version of the corresponding region of src. The median filter replaces each pixel with the median value underneath the width x height window surrounding it. If height <= 0, it will be set to width, making a square window.

Median filters are good for removing high-frequency detail smaller than the window size (including noise), without blurring edges that are larger than the window size.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::median_filter(ImageBuf &dst, const ImageBuf &src, int width =  
3, int height = -1, ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Noisy ("tahoe.exr");  
ImageBuf Clean = ImageBufAlgo::median_filter (Noisy, 3, 3);
```

Python

```
Noisy = ImageBuf("tahoe.exr")  
Clean = ImageBufAlgo.median_filter (Noisy, 3, 3)
```

oiitool

```
oiitool tahoe.exr --median 3x3 -o clean.exr
```

```
ImageBuf OIIO::ImageBufAlgo::unsharp_mask(const ImageBuf &src, string_view kernel = "gaussian", float
width = 3.0f, float contrast = 1.0f, float threshold = 0.0f, ROI
roi = {}, int nthreads = 0)
```

Return a sharpened version of the corresponding region of `src` using the “unsharp mask” technique. Unsharp masking basically works by first blurring the image (low pass filter), subtracting this from the original image, then adding the residual back to the original to emphasize the edges. Roughly speaking,

```
dst = src + contrast * thresh(src - blur(src))
```

The specific blur can be selected by kernel name and width (for example, “gaussian” is typical). As a special case, “median” is also accepted as the kernel name, in which case a median filter is performed rather than a blurring convolution (Gaussian and other blurs sometimes over-sharpen edges, whereas using the median filter will sharpen compact high-frequency details while not over-sharpening long edges).

The `contrast` is a multiplier on the overall sharpening effect. The thresholding step causes all differences less than `threshold` to be squashed to zero, which can be useful for suppressing sharpening of low-contrast details (like noise) but allow sharpening of higher-contrast edges.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::unsharp_mask(ImageBuf &dst, const ImageBuf &src, string_view
kernel = "gaussian", float width = 3.0f, float
contrast = 1.0f, float threshold = 0.0f, ROI roi = {},
int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Blurry ("tahoe.exr");
ImageBuf Sharp = ImageBufAlgo::unsharp_mask (Blurry, "gaussian", 5.0f);
```

Python

```
Blurry ImageBuf("tahoe.exr")
Sharp = ImageBufAlgo.unsharp_mask (Blurry, "gaussian", 5.0)
```

oiio tool

```
oiiotool tahoe.exr --unsharp:kernel=gaussian:width=5 -o sharp.exr
```

10.8 Morphological filters

`ImageBuf OIIO::ImageBufAlgo::dilate`(const `ImageBuf` &src, int width = 3, int height = -1, *ROI* roi = {}, int nthreads = 0)

Return a dilated version of the corresponding region of `src`. Dilation is defined as the maximum value of all pixels under nonzero values of the structuring element (which is taken to be a width x height square). If height is not set, it will default to be the same as width. Dilation makes bright features wider and more prominent, dark features thinner, and removes small isolated dark spots.

Result-as-parameter version:

`bool OIIO::ImageBufAlgo::dilate`(`ImageBuf` &dst, const `ImageBuf` &src, int width = 3, int height = -1, *ROI* roi = {}, int nthreads = 0)

Write to an existing image `dst` (allocating if it is uninitialized).

`ImageBuf OIIO::ImageBufAlgo::erode`(const `ImageBuf` &src, int width = 3, int height = -1, *ROI* roi = {}, int nthreads = 0)

Return an eroded version of the corresponding region of `src`. Erosion is defined as the minimum value of all pixels under nonzero values of the structuring element (which is taken to be a width x height square). If height is not set, it will default to be the same as width. Erosion makes dark features wider, bright features thinner, and removes small isolated bright spots.

Result-as-parameter version:

`bool OIIO::ImageBufAlgo::erode`(`ImageBuf` &dst, const `ImageBuf` &src, int width = 3, int height = -1, *ROI* roi = {}, int nthreads = 0)

Write to an existing image `dst` (allocating if it is uninitialized).

Dilation and erosion are basic morphological filters, and more complex ones are often constructed from them:

- “open” is erode followed by dilate, and it keeps the overall shape while removing small bright regions;
- “close” is dilate followed by erode, and it keeps the overall shape while removing small dark regions;
- “morphological gradient” is dilate minus erode, which gives a bright perimeter edge;
- “tophat” is the original source minus the “open”, which isolates local peaks;
- “bottomhat” is the “close” minus the original source, which isolates dark holes.

Examples:

C++

```

ImageBuf Source ("source.tif");

ImageBuf Dilated = ImageBufAlgo::dilate (Source, 3, 3);
ImageBuf Eroded  = ImageBufAlgo::erode (Source, 3, 3);

// Morphological "open" is dilate(erode((source))
ImageBuf Opened = ImageBufAlgo::dilate (Eroded, 3, 3);
// Morphological "close" is erode(dilate(source))
ImageBuf Closed = ImageBufAlgo::erode (Dilated, 3, 3);
// Morphological "gradient" is dilate minus erode
ImageBuf Gradient = ImageBufAlgo::sub (Dilated, Eroded);
// Tophat filter is source minus open
ImageBuf Tophat = ImageBufAlgo::sub (Source, Opened);
// Bottomhat filter is close minus source
ImageBuf Bottomhat = ImageBufAlgo::sub (Close, Source);

```

Python

```

Source = ImageBuf("source.tif")

Dilated = ImageBufAlgo.dilate (Source, 3, 3)
Eroded  = ImageBufAlgo.erode (Source, 3, 3)

# Morphological "open" is dilate(erode((source))
Opened = ImageBufAlgo.dilate (Eroded, 3, 3)
# Morphological "close" is erode(dilate(source))
Closed = ImageBufAlgo.erode (Dilated, 3, 3)
# Morphological "gradient" is dilate minus erode
Gradient = ImageBufAlgo.sub (Dilated, Eroded)
# Tophat filter is source minus open
Tophat = ImageBufAlgo.sub (Source, Opened)
# Bottomhat filter is close minus source
Bottomhat = ImageBufAlgo.sub (Close, Source)

```

oiiotool

```

oiiotool source.tif --dilate 3x3 -o dilated.tif
oiiotool source.tif --erode 3x3 -o eroded.tif

# Morphological "open" is dilate(erode((source))
oiiotool source.tif --erode 3x3 --dilate 3x3 -o opened.tif
# Morphological "close" is erode(dilate(source))
oiiotool source.tif --dilate 3x3 --erode 3x3 -o closed.tif
# Morphological "gradient" is dilate minus erode
oiiotool source.tif --dilate 3x3 source.tif --erode 3x3 --sub -o gradient.
↳tif
# Tophat filter is source minus open
oiiotool source.tif source.tif --erode 3x3 --dilate 3x3 --sub -o tophat.tif
# Bottomhat filter is close minus source
oiiotool source.tif --dilate 3x3 --erode 3x3 source.tif --sub -o bottomhat.
↳tif

```

10.9 Color space conversion

group **colorconvert**

Convert between color spaces

Return (or copy into `dst`) the pixels of `src` within the *ROI*, applying a color space transformation. In-place operations (`dst == src`) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is presumed to be alpha. Any additional channels will be simply copied unaltered.

If OIIO was built with OpenColorIO support enabled, then the transformation may be between any two spaces supported by the active OCIO configuration, or may be a “look” transformation created by `ColorConfig::createLookTransform`. If OIIO was not built with OpenColorIO support enabled, then the only transformations available are from “sRGB” to “linear” and vice versa.

param fromspace/tospace

For the varieties of `colorconvert()` that use named color spaces, these specify the color spaces by name.

param context_key/context_value

For the varieties of `colorconvert()` that use named color spaces, these optionally specify a “key” name/value pair to establish a context (for example, a shot-specific transform).

param processor

For the varieties of `colorconvert()` that have a `processor` parameter, it is a raw `ColorProcessor*` object that implements the color transformation. This is a special object created by a `ColorConfig` (see `OpenImageIO/color.h` for details).

param unpremult

If true, unpremultiply the image (divide the RGB channels by alpha if it exists and is nonzero) before color conversion, then repremult after the after the color conversion. Passing `unpremult=false` skips this step, which may be desirable if you know that the image is “unassociated alpha” (a.k.a., “not pre-multiplied colors”).

param colorconfig

An optional `ColorConfig*` specifying an OpenColorIO configuration. If not supplied, the de-

fault OpenColorIO color configuration found by examining the \$OCIO environment variable will be used instead.

Functions

ImageBuf **colorconvert**(const ImageBuf &src, string_view fromspace, string_view tospace, bool unpremult = true, string_view context_key = "", string_view context_value = "", const ColorConfig *colorconfig = nullptr, ROI roi = {}, int nthreads = 0)

Transform between named color spaces, returning an ImageBuf result.

ImageBuf **colorconvert**(const ImageBuf &src, const ColorProcessor *processor, bool unpremult, ROI roi = {}, int nthreads = 0)

Transform using a ColorProcessor, returning an ImageBuf result.

bool **colorconvert**(ImageBuf &dst, const ImageBuf &src, string_view fromspace, string_view tospace, bool unpremult = true, string_view context_key = "", string_view context_value = "", const ColorConfig *colorconfig = nullptr, ROI roi = {}, int nthreads = 0)

Transform between named color spaces, storing results into an existing ImageBuf.

bool **colorconvert**(ImageBuf &dst, const ImageBuf &src, const ColorProcessor *processor, bool unpremult, ROI roi = {}, int nthreads = 0)

Transform using a ColorProcessor, storing results into an existing ImageBuf.

bool **colorconvert**(span<float> color, const ColorProcessor *processor, bool unpremult)

Apply a color transform in-place to just one color: `color[0..nchannels-1]`. `nchannels` should either be 3 or 4 (if 4, the last channel is alpha).

Examples:

C++

```
ImageBuf Src ("tahoe.jpg");
ImageBuf Dst = ImageBufAlgo::colorconvert (Src, "sRGB", "acescg", true);
```

Python

```
Src = ImageBuf("tahoe.jpg")
Dst = ImageBufAlgo.colorconvert (Src, "sRGB", "acescg", True)
```

oiiotool

```
oiiotool tahoe.jpg --colorconvert sRGB acescg -o tahoe_acescg.exr
```

ImageBuf OIIO::ImageBufAlgo::**colormatrixtransform**(const ImageBuf &src, M44fParam M, bool unpremult = true, *ROI* roi = {}, int nthreads = 0)

Return a copy of the pixels of `src` within the *ROI*, applying a color transform specified by a 4x4 matrix. In-place operations (`dst == src`) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is presumed to be alpha. Any additional channels will be simply copied unaltered.

Version

2.1+

Parameters

- **M** – A 4x4 matrix. Following Imath conventions, the color is a row vector and the matrix has the “translation” part in elements [12..14] (matching the memory layout of OpenGL or RenderMan), so the math is `color * Matrix` (NOT `M*c`).
- **unpremult** – If true, unpremultiply the image (divide the RGB channels by alpha if it exists and is nonzero) before color conversion, then repremult after the after the color conversion. Passing `unpremult=false` skips this step, which may be desirable if you know that the image is “unassociated alpha” (a.k.a., “not pre-multiplied colors”).

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::colormatrixtransform(ImageBuf &dst, const ImageBuf &src,
                                              M44fParam M, bool unpremult = true,
                                              ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Src ("tahoe.exr");
Imath::M44f M ( .8047379, .5058794, -.3106172, 0,
                -.3106172, .8047379, .5058794, 0,
                .5058794, -.3106172, .8047379, 0,
                0, 0, 0, 1);
ImageBuf dst = ImageBufAlgo::colormatrixtransform (Src, M);
```

Python

```
Src = ImageBuf("tahoe.exr")
M = ( .8047379, .5058794, -.3106172, 0,
      -.3106172, .8047379, .5058794, 0,
      .5058794, -.3106172, .8047379, 0,
      0, 0, 0, 1 )
dst = ImageBufAlgo.colormatrixtransform (Src, M)
```

oiio tool

```
oiio tool tahoe.exr --colormatrixtransform 0.8047379,0.5058794,-0.
↪3106172,0,-0.3106172,0.8047379,0.5058794,0.5058794,-0.3106172,0,0,0,
↪0,1,0 -o tahoe_matrix.exr
```

```
ImageBuf OIIO::ImageBufAlgo::ociolook(const ImageBuf &src, string_view looks, string_view fromspace,
                                     string_view tospace, bool unpremult = true, bool inverse = false,
                                     string_view context_key = "", string_view context_value = "", const
                                     ColorConfig *colorconfig = nullptr, ROI roi = {}, int nthreads = 0)
```

Return a copy of the pixels of `src` within the *ROI*, applying an OpenColorIO “look” transform to the pixel values. In-place operations (`dst == src`) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is presumed to be alpha. Any additional channels will be simply copied unaltered.

Parameters

- **looks** – The looks to apply (comma-separated).
- **fromspace/tospace** – For the varieties of `colorconvert()` that use named color spaces, these specify the color spaces by name.
- **unpremult** – If true, unpremultiply the image (divide the RGB channels by alpha if it exists and is nonzero) before color conversion, then repremult after the after the color conversion. Passing `unpremult=false` skips this step, which may be desirable if you know that the image is “unassociated alpha” (a.k.a., “not pre-multiplied colors”).
- **inverse** – If true, it will reverse the color transformation and look application.
- **context_key/context_value** – Optional key/value to establish a context (for example, a shot-specific transform).
- **colorconfig** – An optional `ColorConfig*` specifying an OpenColorIO configuration. If not supplied, the default OpenColorIO color configuration found by examining the `$OCIO` environment variable will be used instead.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::ociolook(ImageBuf &dst, const ImageBuf &src, string_view
                                  looks, string_view fromspace, string_view tospace, bool
                                  unpremult = true, bool inverse = false, string_view
                                  context_key = "", string_view context_value = "", const
                                  ColorConfig *colorconfig = nullptr, ROI roi = {}, int
                                  nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Src ("tahoe.jpg");
ImageBuf Dst = ImageBufAlgo::ociolook (Src, "look", "vd8", "lnf",
                                     true, false, "SHOT", "pe0012");
```

Python

```
Src = ImageBuf("tahoe.jpg")
Dst = ImageBufAlgo.ociolook (Src, "look", "vd8", "lnf",
                             True, False, "SHOT", "pe0012")
```

oiioool

```
oiiotool tahoe.jpg --  
ociolook:from=vd8:to=lnf:unpremult=1:key=SHOT:value=pe0012 look -o  
out.exr
```

`ImageBuf OIIO::ImageBufAlgo::ociodisplay`(const ImageBuf &src, string_view display, string_view view, string_view fromspace = "", string_view looks = "", bool unpremult = true, bool inverse = false, string_view context_key = "", string_view context_value = "", const ColorConfig *colorconfig = nullptr, *ROI* roi = {}, int nthreads = 0)

Return the pixels of `src` within the *ROI*, applying an OpenColorIO “display” transform to the pixel values. In-place operations (`dst == src`) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is presumed to be alpha. Any additional channels will be simply copied unaltered.

Parameters

- **display** – The OCIO “display” to apply. If this is “default” or the empty string “”, the default display will be used.
- **view** – The OCIO “view” to use. If this is “default” or the empty string “”, the default view for this display will be used.
- **fromspace** – If `fromspace` is not supplied, it will assume that the source color space is whatever is indicated by the source image’s metadata or filename, and if that cannot be deduced, it will be assumed to be scene linear.
- **looks** – The looks to apply (comma-separated). This may be empty, in which case no “look” is used. Note: this parameter value is not used when building against OpenColorIO 2.x.
- **unpremult** – If true, unpremultiply the image (divide the RGB channels by alpha if it exists and is nonzero) before color conversion, then repremult after the after the color conversion. Passing `unpremult=false` skips this step, which may be desirable if you know that the image is “unassociated alpha” (a.k.a., “not pre-multiplied colors”).
- **inverse** – If true, it will reverse the color transformation and display application.
- **context_key/context_value** – Optional key/value to establish a context (for example, a shot-specific transform).
- **colorconfig** – An optional `ColorConfig*` specifying an OpenColorIO configuration. If not supplied, the default OpenColorIO color configuration found by examining the `$OCIO` environment variable will be used instead.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::ociodisplay(ImageBuf &dst, const ImageBuf &src, string_view  
display, string_view view, string_view fromspace =  
"", string_view looks = "", bool unpremult = true,  
bool inverse = false, string_view context_key = "",  
string_view context_value = "", const ColorConfig  
*colorconfig = nullptr, ROI roi = {}, int nthreads =  
0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Src ("tahoe.exr");
ImageBuf Dst = ImageBufAlgo::ociodisplay (Src, "sRGB", "Film", "lnf",
                                          "", true, "SHOT", "pe0012");
```

Python

```
Src = ImageBuf("tahoe.jpg")
Dst = ImageBufAlgo.ociodisplay (Src, "sRGB", "Film", "lnf",
                                "", True, "SHOT", "pe0012")
```

oiiotool

```
oiiotool tahoe.jpg --
❯ociodisplay:from=lnf:unpremult=1:key=SHOT:value=pe0012 sRGB Film -o_
❯out.exr
```

`ImageBuf OIIO::ImageBufAlgo::ociofiletransform`(const ImageBuf &src, string_view name, bool unpremult = true, bool inverse = false, const ColorConfig *colorconfig = nullptr, *ROI* roi = {}, int nthreads = 0)

Return the pixels of `src` within the *ROI*, applying an OpenColorIO “file” transform. In-place operations (`dst == src`) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is presumed to be alpha. Any additional channels will be simply copied unaltered.

Parameters

- **name** – The name of the file containing the transform information.
- **unpremult** – If true, unpremultiply the image (divide the RGB channels by alpha if it exists and is nonzero) before color conversion, then repremult after the after the color conversion. Passing `unpremult=false` skips this step, which may be desirable if you know that the image is “unassociated alpha” (a.k.a., “not pre-multiplied colors”).
- **inverse** – If true, it will reverse the color transformation.
- **colorconfig** – An optional ColorConfig* specifying an OpenColorIO configuration. If not supplied, the default OpenColorIO color configuration found by examining the \$OCIO environment variable will be used instead.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::ociofiletransform(ImageBuf &dst, const ImageBuf &src,
                                          string_view name, bool unpremult = true,
                                          bool inverse = false, const ColorConfig
                                          *colorconfig = nullptr, ROI roi = {}, int
                                          nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Src ("tahoe.exr");
ImageBuf Dst = ImageBufAlgo::ociofiletransform (Src, "footransform.csp
↪");
```

Python

```
Src = ImageBuf("tahoe.exr")
Dst = ImageBufAlgo.ociofiletransform (Src, "footransform.csp")
```

oiiotool

```
oiiotool tahoe.exr --ociofiletransform:unpremult=1 footransform.csp -o↪
↪out.exr
```

group **premult**

Premultiply or un-premultiply color by alpha

The **unpremult** operation returns (or copies into **dst**) the pixels of **src** within the *ROI*, and in the process divides all color channels (those not alpha or z) by the alpha value, to “un-premultiply” them. This presumes that the image starts of as “associated alpha” a.k.a. “premultiplied,” and you are converting to “unassociated alpha.” For pixels with alpha == 0, the color values are not modified.

The **premult** operation returns (or copies into **dst**) the pixels of **src** within the *ROI*, and in the process multiplies all color channels (those not alpha or z) by the alpha value, to “premultiply” them. This presumes that the image starts of as “unassociated alpha” a.k.a. “non-premultiplied” and converts it to “associated alpha / premultiplied.”

The **repremult** operation is like **premult**, but preserves the color values of pixels whose alpha is 0. This is intended for cases where you unpremult, do an operation (such as color transforms), then want to return to associated/premultiplied alpha — in that case, you want to make sure that “glow” pixels (those with alpha=0 but RGB > 0) are preserved for the round trip, and not crushed to black. This use case is distinct from a simple **premult** that is a one-time conversion from unassociated to associated alpha.

All three operations are simply a copy if there is no identified alpha channel (and a no-op if **dst** and **src** are the same image).

Functions

ImageBuf **unpremult**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **unpremult**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

ImageBuf **premult**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **premult**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

ImageBuf **repremult**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **repremult**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:

C++

```

// Convert from unassociated alpha to associated alpha by
// straightforward multiplication of color by alpha.
ImageBuf Unassoc; // Assume somehow this has unassociated alpha
ImageBuf Assoc = ImageBufAlgo::premult (Unassoc);

// Convert in-place from associated alpha to unassociated alpha,
// preserving the color of alpha==0 pixels.
ImageBuf A;
ImageBufAlgo::unpremult (A, A);

// Finish the round-trip back to associated, still preserving the
// color of alpha==0 pixels. This should result in exactly the same
// pixel values we started with (within precision limits).
ImageBufAlgo::repremult (A, A);

```

Python

```

# Convert from unassociated alpha to associated alpha by
# straightforward multiplication of color by alpha.
Unassoc = ImageBuf(...) # Assume somehow this has unassociated alpha
Assoc = ImageBufAlgo.premult (Unassoc)

# Convert in-place from associated alpha to unassociated alpha,
# preserving the color of alpha==0 pixels.
A = ImageBuf(...)
ImageBufAlgo.unpremult (A, A)

# Finish the round-trip back to associated, still preserving the
# color of alpha==0 pixels. This should result in exactly the same
# pixel values we started with (within precision limits).
ImageBufAlgo.repremult (A, A)

```

oiiotool

```

# Convert from unassociated alpha to associated alpha by
# straightforward multiplication of color by alpha.
oiiotool unassoc.tif --premult -o assoc.tif

# Convert in-place from associated alpha to unassociated alpha,
# preserving the color of alpha==0 pixels.
oiiotool A.tif --unpremult -o A.tif

# Finish the round-trip back to associated, still preserving the
# color of alpha==0 pixels. This should result in exactly the same
# pixel values we started with (within precision limits).
oiiotool A.tif --repremult -o A.tif

```

10.10 Import / export

group **make_texture**

The `make_texture()` function turns an image into a tiled, MIP-mapped, texture file and write it to disk (outputfilename).

The return value is `true` for success, `false` if an error occurred. If there was an error, any error message will be retrievable via the global `OIIO::geterror()` call (since there is no destination `ImageBuf` in which to store it).

Named fields in config:

- `format` : Data format of the texture file (default: UNKNOWN = same format as the input)
- `tile_width/tile_height/tile_depth` : Preferred tile size (default: 64x64x1)

Metadata in `config.extra_attribs`

- `compression` (string) : Default: "zip"
- `fovcot` (float) : Default: aspect ratio of the image resolution.
- `planarconfig` (string) : Default: "separate"
- `worldtocamera` (matrix) : World-to-camera matrix of the view.
- `worldtoscreen` (matrix) : World-to-screen space matrix of the view.
- `worldtoNDC` (matrix) : World-to-NDC space matrix of the view.
- `wrapmodes` (string) : Default: "black,black"
- `handed` (string) : "left" or "right" reveals the handedness of the coordinates for normal maps. ("")
- `maketx:verbose` (int) : How much detail should go to outstream (0).
- `maketx:runstats` (int) : If nonzero, print run stats to outstream (0).
- `maketx:resize` (int) : If nonzero, resize to power of 2. (0)
- `maketx:nomipmap` (int) : If nonzero, only output the top MIP level (0).
- `maketx:updatemode` (int) : If nonzero, write new output only if the output file doesn't already exist, or is older than the input file, or was created with different command-line arguments. (0)
- `maketx:constant_color_detect` (int) : If nonzero, detect images that are entirely one color, and change them to be low resolution (default: 0).
- `maketx:monochrome_detect` (int) : If nonzero, change RGB images which have R==G==B everywhere to single-channel grayscale (default: 0).
- `maketx:opaque_detect` (int) : If nonzero, drop the alpha channel if alpha is 1.0 in all pixels (default: 0).
- `maketx:compute_average` (int) : If nonzero, compute and store the average color of the texture (default: 1).
- `maketx:unpremult` (int) : If nonzero, unpremultiply color by alpha before color conversion, then multiply by alpha after color conversion (default: 0).
- `maketx:incolospace, maketx:outcolospace` (string) : These two together will apply a color conversion (with `OpenColorIO`, if compiled). Default: ""
- `maketx:colorconfig` (string) : Specifies a custom `OpenColorIO` color config file. Default: ""

- **maketx:checknan** (int) : If nonzero, will consider it an error if the input image has any NaN pixels. (0)
- **maketx:fixnan** (string) : If set to “black” or “box3”, will attempt to repair any NaN pixels found in the input image (default: “none”).
- **maketx:set_full_to_pixels** (int) : If nonzero, doctors the full/display window of the texture to be identical to the pixel/data window and reset the origin to 0,0 (default: 0).
- **maketx:filtername** (string) : If set, will specify the name of a high-quality filter to use when resampling for MIPmap levels. Default: “”, use bilinear resampling.
- **maketx:highlightcomp** (int) : If nonzero, performs highlight compensation & range compression and expansion around the resize, plus clamping negative pixel values to zero. This reduces ringing when using filters with negative lobes on HDR images.
- **maketx:sharpen** (float) : If nonzero, sharpens details when creating MIPmap levels. The amount is the contrast metric. The default is 0, meaning no sharpening.
- **maketx:nchannels** (int) : If nonzero, will specify how many channels the output texture should have, padding with 0 values or dropping channels, if it doesn’t the number of channels in the input. (default: 0, meaning keep all input channels)
- **maketx:channelnames** (string) : If set, overrides the channel names of the output image (comma-separated).
- **maketx:fileformatname** (string) : If set, will specify the output file format. (default: “”, meaning infer the format from the output filename)
- **maketx:oio_options** (int) : (Deprecated; all are handled by default)
- **maketx:prman_options** (int) : If nonzero, override a whole bunch of settings as needed to make textures that are compatible with PRMan. This also enables prman_metadata. (0)
- **maketx:prman_metadata** (int) : If set, output some metadata that PRMan will need for its textures. (0)
- **maketx:mipimages** (string) : Semicolon-separated list of alternate images to be used for individual MIPmap levels, rather than simply downsizing. (default: “”)
- **maketx:mipmap_metadata** (int) : If nonzero, will propagate metadata to every MIP level. The default (0) only writes metadata to the highest-resolution level. (0)
- **maketx:full_command_line** (string) : The command or program used to generate this call, will be embedded in the metadata. (default: “”)
- **maketx:ignore_unassoc** (int) : If nonzero, will disbelieve any evidence that the input image is unassociated alpha. (0)
- **maketx:read_local_MB** (int) : If nonzero, will read the full input file locally if it is smaller than this threshold. Zero causes the system to make a good guess at a reasonable threshold (e.g. 1 GB). (0)
- **maketx:forcefloat** (int) : Forces a conversion through float data for the sake of ImageBuf math. (1)
- **maketx:hash** (int) : Compute the sha1 hash of the file in parallel. (1)
- **maketx:allow_pixel_shift** (int) : Allow up to a half pixel shift per mipmap level. The fastest path may result in a slight shift in the image, accumulated for each mip level with an odd resolution. (0)
- **maketx:bumpformat** (string) : For the MakeTxBumpWithSlopes mode, chooses whether to assume the map is a height map (“height”), a normal map (“normal”), or automatically determine it from the number of channels (“auto”, the default).
- **maketx:uvslopes_scale** (float) : If nonzero, when used in MakeTxBumpWithSlopes mode, this computes derivatives for the bumpslopes data in UV space rather than in texel space, and divides them by this scale factor. The default is 0, disabling the feature. If you use this feature, a suggested value is 256.

- **maketx:cdf** (int) : If nonzero, will write a Gaussian CDF and Inverse Gaussian CDF as per-channel metadata in the texture, which can be used by shaders to implement Histogram-Preserving Blending. This is only useful when the texture being created is written to an image format that supports arbitrary metadata (e.g. OpenEXR). (See Burley, “On Histogram-Preserving Blending for Randomized Texture Tiling,” JCGT 8(4), 2019, and Heitz/Neyret, “High-Performance By-Example Noise using a Histogram-Preserving Blending Operator,” ACM SIGGRAPH / Eurographics Symposium on High-Performance Graphics 2018.) (default: 0)
- **maketx:cdfsigma** (float) : When **maketx:cdf** is active, determines the CDF sigma (default: 1.0/6).
- **maketx:cdfbits** (int) : When **maketx:cdf** is active, determines the number of bits to use for the size of the CDF table. (default: 8, meaning 256 bins)

param mode

Describes what type of texture file we are creating and may be one of:

- **MakeTxTexture** : Ordinary 2D texture.
- **MakeTxEnvLat1** : Latitude-longitude environment map
- **MakeTxEnvLat1FromLightProbe** : Latitude-longitude environment map constructed from a “light probe” image.
- **MakeTxBumpWithSlopes** : Bump/displacement map with extra slope data channels (6 channels total, containing both the height and 1st and 2nd moments of slope distributions) for bump-to-roughness conversion in shaders.

param outputfilename

Name of the file in which to save the resulting texture.

param config

An *ImageSpec* that contains all the information and special instructions for making the texture. Anything set in config (format, tile size, or named metadata) will take precedence over whatever is specified by the input file itself. Additionally, named metadata that starts with “maketx:” will not be output to the file itself, but may contain instructions controlling how the texture is created. The full list of supported configuration options is listed below.

param ostream

If not `nullptr`, it should point to a stream (for example, `&std::out`, or a pointer to a local `std::stringstream` to capture output), which is where console output and errors will be deposited. Note that error messages will also be retrievable from `OIO::geterror()`.

Functions

bool **make_texture**(MakeTextureMode mode, const ImageBuf &input, string_view outputfilename, const ImageSpec &config, std::ostream *ostream = nullptr)

Version of `make_texture` that starts with an `ImageBuf`.

bool **make_texture**(MakeTextureMode mode, string_view filename, string_view outputfilename, const ImageSpec &config, std::ostream *ostream = nullptr)

Version of `make_texture` that starts with a filename and reads the input from that file, rather than being given an `ImageBuf` directly.

bool **make_texture**(MakeTextureMode mode, const std::vector<std::string> &filenames, string_view outputfilename, const ImageSpec &config, std::ostream *ostream = nullptr)

Version of `make_texture` that takes multiple filenames (reserved for future expansion, such as assembling several faces into a cube map).

Examples:

C++

```
ImageBuf Input ("grid.exr");
ImageSpec config;
config["maketx:highlightcomp"] = 1;
config["maketx:filtername"] = "lanczos3";
config["maketx:opaque_detect"] = 1;

bool ok = ImageBufAlgo::make_texture (ImageBufAlgo::MakeTxTexture,
                                     Input, "texture.exr", config);
if (! ok)
    std::cout << "make_texture error: " << OIIO::geterror() << "\n";
```

Python

```
Input = ImageBuf("grid.exr")
config = ImageSpec()
config["maketx:highlightcomp"] = 1
config["maketx:filtername"] = "lanczos3"
config["maketx:opaque_detect"] = 1

ok = ImageBufAlgo.make_texture (oiio.MakeTxTexture,
                                Input, "texture.exr", config)
if not ok :
    print("make_texture error:", oiio.geterror())
```

oiiotool

```
oiiotool in.exr -otex:highlightcomp=1:filtername=lanczos3:opaque_
detect=1 texture.exr
```

maketx

```
maketx in.exr --hicomp --filter lanczos3 --opaque-detect -o texture.exr
```

OpenCV interoperability is performed by the `from_OpenCV()` and `to_OpenCV()` functions:

```
inline ImageBuf OIIO::ImageBufAlgo::from_OpenCV(const cv::Mat &mat, TypeDesc convert = TypeUnknown,
                                                ROI roi = {}, int nthreads = 0)
```

Convert an OpenCV `cv::Mat` into an ImageBuf, copying the pixels (optionally converting to the pixel data type specified by `convert`, if not UNKNOWN, which means to preserve the original data type if possible). Return true if ok, false if it was not able to make the conversion from Mat to ImageBuf. Any error messages can be retrieved by calling `geterror()` on the returned ImageBuf. If OpenImageIO was compiled without OpenCV support, this function will return false.

```
inline bool OIIO::ImageBufAlgo::to_OpenCV(cv::Mat &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
```

Construct an OpenCV `cv::Mat` containing the contents of ImageBuf `src`, and return true. If it is not possible, or

if OpenImageIO was compiled without OpenCV support, then return false. Any error messages can be retrieved by calling `OIO::geterror()`. Note that OpenCV only supports up to 4 channels, so >4 channel images will be truncated in the conversion.

```
inline ImageBuf OIO::ImageBufAlgo::capture_image(int cameranum = 0, TypeDesc convert =  
                                                TypeUnknown)
```

Capture a still image from a designated camera. If able to do so, store the image in `dst` and return true. If there is no such device, or support for camera capture is not available (such as if OpenCV support was not enabled at compile time), return false and do not alter `dst`.

Examples:

```
ImageBuf WebcamImage = ImageBufAlgo::capture_image (0, TypeDesc::UINT8);  
WebcamImage.write ("webcam.jpg");
```

10.11 Deep images

A number of `ImageBufAlgo` functions are designed to work with “deep” images. These are detailed below. In general, `ImageBufAlgo` functions not listed in this section should not be expected to work with deep images.

10.11.1 Functions specific to deep images

```
ImageBuf OIO::ImageBufAlgo::deepen(const ImageBuf &src, float zvalue = 1.0f, ROI roi = {}, int nthreads =  
0)
```

Return the “deep” equivalent of the “flat” input `src`. Turning a flat image into a deep one means:

- If the `src` image has a “Z” channel: if the source pixel’s Z channel value is not infinite, the corresponding pixel of `dst` will get a single depth sample that copies the data from the source pixel; otherwise, `dst` will get an empty pixel. In other words, infinitely far pixels will not turn into deep samples.
- If the `src` image lacks a “Z” channel: if any of the source pixel’s channel values are nonzero, the corresponding pixel of `dst` will get a single depth sample that copies the data from the source pixel and uses the `zvalue` parameter for the depth; otherwise, if all source channels in that pixel are zero, the destination pixel will get no depth samples.

If `src` is already a deep image, it will just copy pixel values from `src`.

Result-as-parameter version:

```
bool OIO::ImageBufAlgo::deepen(ImageBuf &dst, const ImageBuf &src, float zvalue = 1.0f,  
ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Flat ("RGBAZ.exr");  
ImageBuf Deep = ImageBufAlgo::deepen (Flat);
```

Python

```
Flat = ImageBuf("RGBAZ.exr")
Deep = ImageBufAlgo.deepen (Flat)
```

oiitool

```
oiitool RGBAZ.exr --deepen -o deep.exr
```

ImageBuf OIIO::ImageBufAlgo::flatten(const ImageBuf &src, *ROI* roi = {}, int nthreads = 0)

Return the “flattened” composite of deep image *src*. That is, it converts a deep image to a simple flat image by front-to-back compositing the samples within each pixel. If *src* is already a non-deep/flat image, it will just copy pixel values from *src* to *dst*. If *dst* is not already an initialized ImageBuf, it will be sized to match *src* (but made non-deep).

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::flatten(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int
                                nthreads = 0)
```

Write to an existing image *dst* (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Deep ("deepalpha.exr");
ImageBuf Flat = ImageBufAlgo::flatten (Deep);
```

Python

```
Deep = ImageBuf("deepalpha.exr")
Flat = ImageBufAlgo.flatten (Deep)
```

oiitool

```
oiitool deepalpha.exr --flatten -o flat.exr
```

ImageBuf OIIO::ImageBufAlgo::deep_merge(const ImageBuf &A, const ImageBuf &B, bool occlusion_cull = true, *ROI* roi = {}, int nthreads = 0)

Return the deep merge of the samples of deep images *A* and *B*, overwriting any existing samples of *dst* in the *ROI*. If *occlusion_cull* is true, any samples occluded by an opaque sample will be deleted.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::deep_merge(ImageBuf &dst, const ImageBuf &A, const ImageBuf
                                     &B, bool occlusion_cull = true, ROI roi = {}, int
                                     nthreads = 0)
```

Write to an existing image *dst* (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf DeepA ("hardsurf.exr");
ImageBuf DeepB ("volume.exr");
ImageBuf Merged = ImageBufAlgo::deep_merge (DeepA, DeepB);
```

Python

```
DeepA = ImageBuf("hardsurf.exr")
DeepB = ImageBuf("volume.exr")
Merged = ImageBufAlgo.deep_merge (DeepA, DeepB)
```

oiitool

```
oiitool hardsurf.exr volume.exr --deep_merge -o merged.exr
```

`ImageBuf OIIO::ImageBufAlgo::deep_holdout`(const ImageBuf &src, const ImageBuf &holdout, *ROI* roi = {}, int nthreads = 0)

Return the samples of deep image src that are closer than the opaque frontier of deep image holdout, returning true upon success and false for any failures. Samples of src that are farther than the first opaque sample of holdout (for the corresponding pixel) will not be copied to dst. Image holdout is only used as the depth threshold; no sample values from holdout are themselves copied to dst.

Result-as-parameter version:

```
bool OIIO::ImageBufAlgo::deep_holdout(ImageBuf &dst, const ImageBuf &src, const
                                     ImageBuf &holdout, ROI roi = {}, int nthreads =
                                     0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Src ("image.exr");
ImageBuf Holdout ("holdout.exr");
ImageBuf Merged = ImageBufAlgo::deep_holdout (Src, Holdout);
```

Python

```
Src = ImageBuf("image.exr")
Holdout = ImageBuf("holdout.exr")
Merged = ImageBufAlgo.deep_holdout (Src, Holdout)
```

oiitool

```
oiitool image.exr holdout.exr --deep_holdout -o merged.exr
```

10.11.2 General functions that also work for deep images

ImageBuf **channels**(const ImageBuf &src, int nchannels, *cspan*<int> channelorder, *cspan*<float> channelvalues = NULL, *cspan*<std::string> newchannelnames = {}, bool shuffle_channel_names = false)

bool **channels**(ImageBuf &dst, const ImageBuf &src, int nchannels, *cspan*<int> channelorder, *cspan*<float> channelvalues = NULL, *cspan*<std::string> newchannelnames = {}, bool shuffle_channel_names = false)

Reorder, rename, remove, or add channels to a deep image.

bool **compare**(const ImageBuf &A, const ImageBuf &B, float failthresh, float warnthresh, CompareResults &result, ROI roi = {}, int nthreads = 0)

Numerically compare two images.

bool **computePixelStats**(PixelStats &stats, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Compute per-channel statistics about the image.

ImageBuf **crop**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool **crop**(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Crop the specified region of `src`, discarding samples outside the ROI.

ROI **nonzero_region**(const ImageBuf &src, ROI roi = {}, int nthreads = 0)

For “deep” images, this function returns the smallest ROI that contains all pixels that contain depth samples, and excludes the border pixels that contain no depth samples at all.

ImageBuf **add**(const ImageBuf &A, *cspan*<float> B, ROI roi = {}, int nthreads = 0)

bool **add**(ImageBuf &dst, const ImageBuf &A, *cspan*<float> B, ROI roi = {}, int nthreads = 0)

ImageBuf **sub**(const ImageBuf &A, *cspan*<float> B, ROI roi = {}, int nthreads = 0)

bool **sub**(ImageBuf &dst, const ImageBuf &A, *cspan*<float> B, ROI roi = {}, int nthreads = 0)

ImageBuf **mul**(const ImageBuf &A, *cspan*<float> B, ROI roi = {}, int nthreads = 0)

bool **mul**(ImageBuf &dst, const ImageBuf &A, *cspan*<float> B, ROI roi = {}, int nthreads = 0)

ImageBuf **div**(const ImageBuf &A, *cspan*<float> B, ROI roi = {}, int nthreads = 0)

bool **div**(ImageBuf &dst, const ImageBuf &A, *cspan*<float> B, ROI roi = {}, int nthreads = 0)

Add, subtract, multiply, or divide all the samples in a deep image `A` by per-channel values `B[]`.

ImageBuf **fixNonFinite**(const ImageBuf &src, NonFiniteFixMode mode = NONFINITE_BOX3, int *pixelsFixed = nullptr, ROI roi = {}, int nthreads = 0)

bool **fixNonFinite**(ImageBuf &dst, const ImageBuf &src, NonFiniteFixMode mode = NONFINITE_BOX3, int *pixelsFixed = nullptr, ROI roi = {}, int nthreads = 0)

Repair nonfinite (NaN or Inf) values, setting them to 0.0.

ImageBuf **resample**(const ImageBuf &src, bool interpolate = true, ROI roi = {}, int nthreads = 0)

bool **resample**(ImageBuf &dst, const ImageBuf &src, bool interpolate = true, ROI roi = {}, int nthreads = 0)

Compute a resized version of the corresponding portion of `src` (mapping such that the “full” image window of each correspond to each other, regardless of resolution), for each pixel merely copying the closest deep pixel of the source image (no true interpolation is done for deep images).

PYTHON BINDINGS

11.1 Overview

OpenImageIO provides Python language bindings for much of its functionality.

You must ensure that the environment variable `PYTHONPATH` includes the **python** subdirectory of the OpenImageIO installation.

A Python program must import the OpenImageIO package:

```
import OpenImageIO
```

In most of our examples below, we assume that for the sake of brevity, we will alias the package name as follows:

```
import OpenImageIO as oiio
from OpenImageIO import ImageInput, ImageOutput
from OpenImageIO import ImageBuf, ImageSpec, ImageBufAlgo
```

11.2 TypeDesc

The `TypeDesc` class that describes data types of pixels and metadata, described in detail in Section *Data Type Descriptions: TypeDesc*, is replicated for Python.

class BASETYPE

The `BASETYPE` enum corresponds to the C++ `TypeDesc::BASETYPE` and contains the following values:

```
UNKNOWN NONE UINT8 INT8 UINT16 INT16 UINT32 INT32 UINT64 INT64
HALF FLOAT DOUBLE STRING PTR
```

These names are also exported to the OpenImageIO namespace.

class AGGREGATE

The `AGGREGATE` enum corresponds to the C++ `TypeDesc::AGGREGATE` and contains the following values:

```
SCALAR VEC2 VEC3 VEC4 MATRIX33 MATRIX44
```

These names are also exported to the OpenImageIO namespace.

class VECSEMANTICS

The `VECSEMANTICS` enum corresponds to the C++ `TypeDesc::VECSEMANTICS` and contains the following values:

```
NOSEMANTICS COLOR POINT VECTOR NORMAL TIMECODE KEYCODE RATIONAL
```

These names are also exported to the OpenImageIO namespace.

```
TypeUnknown TypeString TypeFloat TypeHalf
TypeInt TypeUInt TypeInt16 TypeUInt16
TypeColor TypePoint TypeVector TypeNormal
TypeFloat2 TypeVector2 TypeFloat4
TypeVector2i TypeVector3i
TypeMatrix TypeMatrix33
TypeTimeCode TypeKeyCode TypeRational TypePointer
```

Pre-constructed TypeDesc objects for some common types, available in the outer OpenImageIO scope.

Example:

```
t = TypeFloat
```

str(*typedesc*)

Returns a string that describes the TypeDesc.

Example:

```
print (str(TypeDesc(oio.UINT16)))
> int16
```

TypeDesc.basetype

TypeDesc.aggregate

TypeDesc.vecsemantics

TypeDesc.arraylen

Access to the raw fields in the TypeDesc.

Example:

```
t = TypeDesc(...)
if t.basetype == oio.FLOAT :
    print ("It's made of floats")
```

int TypeDesc.size ()

int TypeDesc.basesize ()

TypeDesc TypeDesc.elementtype ()

int TypeDesc.numelements ()

int TypeDesc.elementsize ()

The size() is the size in bytes, of the type described. The basesize() is the size in bytes of the BASETYPE.

The elementtype() is the type of each array element, if it is an array, or just the full type if it is not an array. The elementsizesize() is the size, in bytes, of the elementtype (thus, returning the same value as size() if the type is not an array). The numelements() method returns arraylen if it is an array, or 1 if it is not an array.

Example:

```

t = TypeDesc("point[2]")
print ("size =", t.size())
print ("elementtype =", t.elementtype())
print ("elementsize =", t.elementsize())

> size = 24
> elementtype = point
> elementsize = 12

```

typedesc == typedesc

typedesc != typedesc

TypeDesc.equivalent(typedesc)

Test for equality or inequality. The `equivalent()` method is more forgiving than `==`, in that it considers POINT, VECTOR, and NORMAL vector semantics to not constitute a difference from one another.

Example:

```

f = TypeDesc("float")
p = TypeDesc("point")
v = TypeDesc("vector")
print ("float==point?", (f == p))
print ("vector==point?", (v == p))
print ("float.equivalent(point)?", f.equivalent(p))
print ("vector.equivalent(point)?", v.equivalent(p))

> float==point? False
> vector==point? False
> float.equivalent(point)? False
> vector.equivalent(point)? True

```

11.3 ROI

The ROI class that describes an image extent or region of interest, explained in detail in Section *Rectangular region of interest: ROI*, is replicated for Python.

ROI()

ROI(xbegin, xend, ybegin, yend, zbegin=0, zend=1, chbegin=0, chend=1000)

Construct an ROI with the given bounds. The constructor with no arguments makes an ROI that is “undefined.”

Example:

```

roi = ROI (0, 640, 0, 480, 0, 1, 0, 4)  # video res RGBA

```

ROI.xbegin

ROI.xend

ROI.ybegin

ROI.yend

ROI.zbegin

ROI.zend

ROI.chbegin

ROI.chend

The basic fields of the ROI (all of type `int`).

ROI.All

A pre-constructed undefined ROI understood to mean unlimited ROI on an image.

ROI.defined

True if the ROI is defined, False if the ROI is undefined.

ROI.width**ROI.height****ROI.depth****ROI.nchannels**

The number of pixels in each dimension, and the number of channels, as described by the ROI. (All of type `int`.)

int ROI.npixels

The total number of pixels in the region described by the ROI (as an `int`).

ROI.contains(*x, y, z=0, ch=0*)

Returns True if the ROI contains the coordinate.

ROI.contains(*other*)

Returns True if the ROI *other* is entirely contained within this ROI.

ROI.get_roi (imagespec)**ROI.get_roi_full (imagespec)**

Returns an ROI corresponding to the pixel data window of the given ImageSpec, or the display/full window, respectively.

Example:

```
spec = ImageSpec(...)
roi = oiio.get_roi(spec)
```

set_roi(imagespec, roi)**set_roi_full(imagespec, roi)**

Alter the ImageSpec's resolution and offset to match the passed ROI.

Example:

```
# spec is an ImageSpec
# The following sets the full (display) window to be equal to the
# pixel data window:
oiio.set_roi_full (spec, oiio.get_roi(spec))
```

11.4 ImageSpec

The ImageSpec class that describes an image, explained in detail in Section *Image Specification: ImageSpec*, is replicated for Python.

ImageSpec()

ImageSpec(typedesc)

ImageSpec(xres, yres, nchannels, typedesc)

ImageSpec(roi, typedesc)

Constructors of an ImageSpec. These correspond directly to the constructors in the C++ bindings.

Example:

```
import OpenImageIO as oiio
...

# default ctr
s = ImageSpec()

# construct with known pixel type, unknown resolution
s = ImageSpec(oiio.UINT8)

# construct with known resolution, channels, pixel data type
s = ImageSpec(640, 480, 4, "half")

# construct from an ROI
s = ImageSpec (ROI(0,640,0,480,0,1,0,3), TypeFloat)
```

ImageSpec.width, ImageSpec.height, ImageSpec.depth

ImageSpec.x, ImageSpec.y, ImageSpec.z

Resolution and offset of the image data (int values).

Example:

```
s = ImageSpec (...)
print ("Data window is ({}, {})-({}, {})"
      .format (s.x, s.x+s.width-1,
              s.y, s.y+s.height-1))
```

ImageSpec.full_width, ImageSpec.full_height, ImageSpec.full_depth

ImageSpec.full_x, ImageSpec.full_y, ImageSpec.full_z

Resolution and offset of the “full” display window (int values).

ImageSpec.tile_width, ImageSpec.tile_height, ImageSpec.tile_depth

For tiled images, the resolution of the tiles (int values). Will be 0 for untiled images.

ImageSpec.format

A TypeDesc describing the pixel data.

ImageSpec.nchannels

An int giving the number of color channels in the image.

ImageSpec.channelnames

A tuple of strings containing the names of each color channel.

ImageSpec.channelformats

If all color channels have the same format, that will be `ImageSpec.format`, and `channelformats` will be `None`. However, if there are different formats per channel, they will be stored in `channelformats` as a tuple of `TypeDesc` objects.

Example:

```
if spec.channelformats == None:
    print ("All color channels are", str(spec.format))
else:
    print ("Channel formats: ")
    for t in spec.channelformats:
        print ("\t", t)
```

ImageSpec.alpha_channel**ImageSpec.z_channel**

The channel index containing the alpha or depth channel, respectively, or -1 if either one does not exist or cannot be identified.

ImageSpec.deep

True if the image is a *deep* (multiple samples per pixel) image, of False if it is an ordinary image.

ImageSpec.extra_attribs

Direct access to the `extra_attribs` named metadata, appropriate for iterating over the entire list rather than searching for a particular named value.

- `len(extra_attribs)` : Returns the number of extra attributes.
- `extra_attribs[i].name` : The name of the indexed attribute.
- `extra_attribs[i].type` : The type of the indexed attribute, as a `TypeDesc`.
- `extra_attribs[i].value` : The value of the indexed attribute.

Example:

```
s = ImageSpec(...)
...
print ("extra_attribs size is", len(s.extra_attribs))
for i in range(len(s.extra_attribs)) :
    print (i, s.extra_attribs[i].name, str(s.extra_attribs[i].type), " :")
    print ("\t", s.extra_attribs[i].value)
print ()
```

Imagespec.roi

The ROI describing the pixel data window.

ImageSpec.roi_full

The ROI describing the “display window” (or “full size”).

ImageSpec.set_format(typedesc)

Given a `TypeDesc`, sets the `format` field and clear any per-channel formats in `channelformats`.

Example:

```
s = ImageSpec ()
s.set_format (TypeDesc("uint8"))
```

ImageSpec.default_channel_names()

Sets `channel_names` to the default names given the value of the `nchannels` field.

ImageSpec.channelindex(name)

Return (as an `int`) the index of the channel with the given name, or -1 if it does not exist.

ImageSpec.channel_bytes()

`ImageSpec.channel_bytes(channel, native=False)` Returns the size of a single channel value, in bytes (as an `int`). (Analogous to the C++ member functions, see Section *Image Specification: ImageSpec* for details.)

ImageSpec.pixel_bytes()

`ImageSpec.pixel_bytes(native=False)`

`ImageSpec.pixel_bytes(chbegin, chend, native=False)`

Returns the size of a pixel, in bytes (as an `int`). (Analogous to the C++ member functions, see Section *Image Specification: ImageSpec* for details.)

ImageSpec.scanline_bytes(native=False)

ImageSpec.tile_bytes(native=False)

ImageSpec.image_bytes(native=False)

Returns the size of a scanline, tile, or the full image, in bytes (as an `int`). (Analogous to the C++ member functions, see Section *Image Specification: ImageSpec* for details.)

ImageSpec.tile_pixels()

ImageSpec.image_pixels()

Returns the number of pixels in a tile or the full image, respectively (as an `int`). (Analogous to the C++ member functions, see Section *Image Specification: ImageSpec* for details.)

ImageSpec.erase_attribute(name, searchtype=TypeUnknown, casesensitive=False)

Remove any specified attributes matching the regular expression `name` from the list of `extra_attribs`.

ImageSpec.attribute(name, int)

ImageSpec.attribute(name, float)

ImageSpec.attribute(name, string)

ImageSpec.attribute(name, typedesc, data)

Sets a metadata value in the `extra_attribs`. If the metadata item is a single `int`, `float`, or `string`, you can pass it directly. For other types, you must pass the `TypeDesc` and then the data (for aggregate types or arrays, pass multiple values as a tuple).

Example:

```
s = ImageSpec (...)
s.attribute("foo_str", "blah")
s.attribute("foo_int", 14)
s.attribute("foo_float", 3.14)
s.attribute("foo_vector", TypeDesc.TypeVector, (1, 0, 11))
s.attribute("foo_matrix", TypeDesc.TypeMatrix,
            (1, 0, 0, 0, 0, 2, 0, 0, 0, 0, 1, 0, 1, 2, 3, 1))
```

ImageSpec.getattribute(name)

ImageSpec.getattribute(name, typedesc)

Retrieves a named metadata value from `extra_attribs`. The generic `getattribute()` function returns it regardless of type, or `None` if the attribute does not exist. The typed variety will only succeed if the attribute is actually of that type specified.

Example:

```
foo = s.getattribute ("foo")    # None if not found
foo = s.getattribute ("foo", oiio.FLOAT) # None if not found AND float
```

`ImageSpec.get_int_attribute(name, defaultval=0)`

`ImageSpec.get_float_attribute(name, defaultval=0.0)`

`ImageSpec.get_string_attribute(name, defaultval="")`

`ImageSpec.get_bytes_attribute(name, defaultval="")`

Retrieves a named metadata value from `extra_attribs`, if it is found and is of the given type; returns the default value (or a passed value) if not found.

For an attribute of type `STRING`, `get_bytes_attribute` in Python3 skips decoding the underlying C string as UTF-8 and returns a bytes object containing the raw byte string.

Example:

```
# If "foo" is not found, or if it's not an int, return 0
foo = s.get_int_attribute ("foo")

# If "foo" is not found, or if it's not a string, return "blah"
foo = s.get_string_attribute ("foo", "blah")
```

ImageSpec[key]

`ImageSpec` provides a Python dict-like interface for metadata, in addition to `attribute()` and `getattribute()`.

The `ImageSpec["key"] = value` notation can be used to set an attribute (just like calling `ImageSpec.attribute("key", value)`). Also, `ImageSpec["key"]` can retrieve an attribute if it is present, or raise a `KeyError` exception if not found.

Like dictionaries, 'key' in `spec` is `True` if the attribute is present, and `del spec['key']` will remove the attribute.

Examples:

```
# Same as: spec.attribute("Compression", comp)
spec["Compression"] = comp

# Same as: comp = spec.getattribute("Compression")
# if it succeeds, or raises a KeyError if not found.
comp = spec["Compression"]

# Failed spec["key"] will raise a KeyError
try:
    r = spec["unknown"]
except:
    print("'unknown' key was not found")

# "key" in spec is True if the key is present
if "Compression" in spec:
    print("'Compression' metadata is present")

# del spec["key"] removes the key
del key["Compression"]
```

(continues on next page)

(continued from previous page)

```
# ImageSpec.get("key") returns the value, or None if not found
comp = spec.get("Compression")
# and optionally, a default value may be passed
comp = spec.get("Compression", "none")
```

The basic ["key"] setting and retrieval was added in OpenImageIO in 2.1. The "key" in and del operators, and the get() method, were added in OpenImageIO 2.4.

ImageSpec.metadata_val(paramval, human=False)

For a ParamValue, format its value as a string.

ImageSpec.serialize(format='text', verbose='Detailed')

Return a string containing the serialization of the ImageSpec. The format may be either "text" or "XML". The verbose may be one of "brief", "detailed", or "detailedhuman".

ImageSpec.to_xml()

Equivalent to serialize("xml", "detailedhuman").

ImageSpec.from_xml(xml)

Initializes the ImageSpec from the information in the string xml containing an XML-serialized ImageSpec.

ImageSpec.channel_name(chan)

Returns a string containing the name of the channel with index chan.

ImageSpec.channelindex(name)

Return the integer index of the channel with the given name, or -1 if the name is not a name of one of the channels.

ImageSpec.channelformat(chan)

Returns a TypeDesc of the channel with index chan.

ImageSpec.get_channelformats()

Returns a tuple containing all the channel formats.

ImageSpec.valid_tile_range(xbegin, xend, ybegin, yend, zbegin, zend)

Returns True if the given tile range exactly covers a set of tiles, or False if it isn't (or if the image is not tiled).

ImageSpec.copy_dimensions(other)

Copies from ImageSpec other only the fields describing the size and data types, but not the arbitrary named metadata or channel names.

bool ImageSpec.set_colorspace (name)

Set metadata to indicate the presumed color space name, or clear all such metadata if name is the empty string.

This function was added in version 2.5.

Example:

```
spec = ImageSpec(...)
spec.set_colorspace ("sRGB")
```

ImageSpec.undefine()

Returns True for a newly initialized (undefined) ImageSpec.

11.4.1 Example: Header info

Here is an illustrative example of the use of ImageSpec, a working Python function that opens a file and prints all the relevant header information:

```
#!/usr/bin/env python
from OpenImageIO import ImageInput

# Print the contents of an ImageSpec
def print_imagespec (spec, subimage=0, mip=0) :

        if input.seek_subimage (sub, mip) :
            continue    # proceed to next subimage
    break # no more MIP levels or subimages
input.close ()

```

11.5 DeepData

The DeepData class describing “deep” image data (multiple depth sample per pixel), which is explained in detail in Section [Reading “deep” data](#), is replicated for Python.

DeepData()

Constructs a DeepData object. It needs to have its `init()` and `alloc()` methods called before it can hold any meaningful data.

DeepData.`init`(*npixels, nchannels, channeltypes, channelnames*)

Initializes this DeepData to hold `npixels` total pixels, with `nchannels` color channels. The data types of the channels are described by `channeltypes`, a tuple of `TypeDesc` values (one per channel), and the names are provided in a tuple of `string`s `channelnames`. After calling `init`, you still need to set the number of samples for each pixel (using `set_nsamples`) and then call `alloc()` to actually allocate the sample memory.

DeepData.`initialized`()

Returns True if the DeepData is initialized at all.

DeepData.`allocated`()

Returns True if the DeepData has already had pixel memory allocated.

DeepData.`pixels`

This `int` field contains the total number of pixels in this collection of deep data.

DeepData.`channels`

This `int` field contains the number of channels.

DeepData.`A_channel`

DeepData.`AR_channel`

DeepData.`AG_channel`

DeepData.`AB_channel`

DeepData.`Z_channel`

DeepData.`Zback_channel`

The channel index of certain named channels, or -1 if they don’t exist. For `AR_channel`, `AG_channel`, `AB_channel`, if they don’t exist, they will contain the value of `A_channel`, and `Zback_channel` will contain the value of `z_channel` if there is no actual Zback.

`DeepData.channelname(c)`

Retrieve the name of channel *C*, as a `string`.

`DeepData.channeltype(c)`

Retrieve the data type of channel *C*, as a `TypeDesc`.

`DeepData.channelsize(c)`

Retrieve the size (in bytes) of one datum of channel *C*.

`DeepData.samplesize()`

Retrieve the packed size (in bytes) of all channels of one sample.

`DeepData.same_channeltypes(other)`

Returns `True` if this `DeepData` has the same channel types as *other*.

`DeepData.set_samples(pixel, nsamples)`

Set the number of samples for a given pixel (specified by integer index).

`DeepData.samples(pixel)`

Get the number of samples for a given pixel (specified by integer index).

`DeepData.insert_samples(pixel, samplepos, n)`

Insert *n* samples starting at the given position of an indexed pixel.

`DeepData.erase_samples(pixel, samplepos, n)`

Erase *n* samples starting at the given position of an indexed pixel.

`DeepData.set_deep_value(pixel, channel, sample, value)`

Set specific float value of a given pixel, channel, and sample index.

`DeepData.set_deep_value_uint(pixel, channel, sample, value)`

Set specific unsigned int value of a given pixel, channel, and sample index.

`DeepData.deep_value(pixel, channel, sample, value)`

Retrieve the specific value of a given pixel, channel, and sample index (for float channels).

`DeepData.deep_value_uint(pixel, channel, sample)`

Retrieve the specific value of a given pixel, channel, and sample index (for uint channels).

`DeepData.copy_deep_sample(pixel, sample, src, srcpixel, srcsample)`

Copy a deep sample from `DeepData src` into this `DeepData`.

`DeepData.copy_deep_pixel(pixel, src, srcpixel)`

Copy a deep pixel from `DeepData src` into this `DeepData`.

`DeepData.split(pixel, depth)`

Split any samples of the pixel that cross *depth*. Return `True` if any splits occurred, `False` if the pixel was unmodified.

`DeepData.sort(pixel)`

Sort the samples of the pixel by their *Z* depth.

`DeepData.merge_overlaps(pixel)`

Merge any adjacent samples in the pixel that exactly overlap in *z* range. This is only useful if the pixel has previously been split at all sample starts and ends, and sorted by depth.

`DeepData.merge_deep_pixels(pixel, src, srcpixel)`

Merge the samples of *src*'s pixel into this `DeepData`'s pixel.

`DeepData.occlusion_cull(pixel)`

Eliminate any samples beyond an opaque sample.

`DeepData.opaque_z(pixel)`

For the given pixel index, return the z value at which the pixel reaches full opacity.

11.6 ImageInput

See Chapter *ImageInput: Reading Images* for detailed explanations of the C++ ImageInput class APIs. The Python APIs are very similar. The biggest difference is that in C++, the various `read_*` functions write the pixel values into an already-allocated array that belongs to the caller, whereas the Python versions allocate and return an array holding the pixel values (or `None` if the read failed).

`ImageInput.open(filename[, config_imagespec])`

Creates an ImageInput object and opens the named file. Returns the open ImageInput upon success, or `None` if it failed to open the file (after which, `OpenImageIO.geterror()` will contain an error message). In the second form, the optional ImageSpec argument `config` contains attributes that may set certain options when opening the file.

Example:

```
input = ImageInput.open ("tahoe.jpg")
if input == None :
    print ("Error:", oiio.geterror())
return
```

`ImageInput.close()`

Closes an open image file, returning `True` if successful, `False` otherwise.

Example:

```
input = ImageInput.open (filename)
...
input.close ()
```

`ImageInput.format_name()`

Returns the format name of the open file, as a string.

Example:

```
input = ImageInput.open (filename)
if input :
    print (filename, "was a", input.format_name(), "file.")
input.close ()
```

`ImageInput.spec()`

Returns an ImageSpec corresponding to the currently open subimage and MIP level of the file.

Example:

```
input = ImageInput.open (filename)
spec = input.spec()
print ("resolution ", spec.width, "x", spec.height)
```

`ImageInput.spec(subimage, miplevel=0)`

Returns a full copy of the ImageSpec corresponding to the designated subimage and MIP level.

ImageSpec ImageInput.spec_dimensions (subimage, miplevel=0)

Returns a partial copy of the ImageSpec corresponding to the designated subimage and MIP level, only copying the dimension fields and not any of the arbitrary named metadata (and is thus much less expensive).

`ImageInput.current_subimage()`

Returns the current subimage of the file.

`ImageInput.current_miplevel()`

Returns the current MIP level of the file.

`ImageInput.seek_subimage(subimage, miplevel)`

Repositions the file pointer to the given subimage and MIP level within the file (starting with 0). This function returns True upon success, False upon failure (which may include the file not having the specified subimage or MIP level).

Example:

```
input = ImageInput.open (filename)
mip = 0
while True :
    ok = input.seek_subimage (0, mip)
    if not ok :
        break
    spec = input.spec()
    print ("MIP level", mip, "is", spec.width, "x", spec.height)
```

`ImageInput.read_image(format='float')`

`ImageInput.read_image(chbegin, chend, format='float')`

`ImageInput.read_image(subimage, miplevel, chbegin, chend, format='float')`

Read the entire image and return the pixels as a NumPy array of values of the given format (described by a TypeDesc or a string, float by default). If the format is unknown, the pixels will be returned in the native format of the file. If an error occurs, None will be returned.

For a normal (2D) image, the array returned will be 3D indexed as [y][x][channel]. For 3D volumetric images, the array returned will be 4D with shape indexed as [z][y][x][channel].

Example:

```
input = ImageInput.open (filename)
spec = input.spec ()
pixels = input.read_image ()
print ("The first pixel is", pixels[0][0])
print ("The second pixel is", pixels[0][1])
input.close ()
```

`ImageInput.read_scanline(y, z, format='float')`

Read scanline number y from depth plane z from the open file, returning the pixels as a NumPy array of values of the given type (described by a TypeDesc or a string, float by default). If the type is TypeUnknown, the pixels will be returned in the native format of the file. If an error occurs, None will be returned.

The pixel array returned will be a 2D ndarray, indexed as [x][channel].

Example:

```

input = ImageInput.open (filename)
spec = input.spec ()
if spec.tile_width == 0 :
    for y in range(spec.y, spec.y+spec.height) :
        pixels = input.read_scanline (y, spec.z, "float")
        # process the scanline
else :
    print ("It's a tiled file")
input.close ()

```

`ImageInput.read_tile(x, y, z, format='float')`

Read the tile whose upper left corner is pixel (x,y,z) from the open file, returning the pixels as a NumPy array of values of the given type (described by a `TypeDesc` or a string, float by default). If the type is `TypeUnknown`, the pixels will be returned in the native format of the file. If an error occurs, `None` will be returned.

For a normal (2D) image, the array of tile pixels returned will be a 3D ndarray indexed as `[y][x][channel]`. For 3D volumetric images, the array returned will be 4D with shape indexed as `[z][y][x][channel]`.

Example:

```

input = ImageInput.open (filename)
spec = input.spec ()
if spec.tile_width > 0 :
    for z in range(spec.z, spec.z+spec.depth, spec.tile_depth) :
        for y in range(spec.y, spec.y+spec.height, spec.tile_height) :
            for x in range(spec.x, spec.x+spec.width, spec.tile_width) :
                pixels = input.read_tile (x, y, z, oio.FLOAT)
                # process the tile
else :
    print ("It's a scanline file")
input.close ()

```

`ImageInput.read_scanlines(subimage, miplevel, ybegin, yend, z, chbegin, chend, format='float')`

`ImageInput.read_scanlines(ybegin, yend, z, chbegin, chend, format='float')`

`ImageInput.read_tiles(xbegin, xend, ybegin, yend, zbegin, zend, chbegin, chend, format='float')`

`ImageInput.read_tiles(subimage, miplevel, xbegin, xend, ybegin, yend, zbegin, zend, format='float')`

Similar to the C++ routines, these functions read multiple scanlines or tiles at once, which in some cases may be more efficient than reading each scanline or tile separately. Additionally, they allow you to read only a subset of channels.

For normal 2D images, both `read_scanlines` and `read_tiles` will return a 3D array indexed as `[z][y][x][channel]`.

For 3D volumetric images, both `read_scanlines` will return a 3D array indexed as `[y][x][channel]`, and `read_tiles` will return a 4D array indexed as `[z][y][x][channel]`,

Example:

```

input = ImageInput.open (filename)
spec = input.spec ()

# Read the whole image, the equivalent of
# pixels = input.read_image (type)
# but do it using read_scanlines or read_tiles:

```

(continues on next page)

(continued from previous page)

```

if spec.tile_width == 0 :
    pixels = input.read_scanlines (spec.y, spec.y+spec.height, 0,
                                   0, spec.nchannels)
else :
    pixels = input.read_tiles (spec.x, spec.x+spec.width,
                              spec.y, spec.y+spec.height,
                              spec.z, spec.z+spec.depth,
                              0, spec.nchannels)

```

`ImageInput.read_native_deep_scanlines(subimage, miplevel, ybegin, yend, z, chbegin, chend)`

`ImageInput.read_native_deep_tiles(subimage, miplevel, xbegin, xend, ybegin, yend, zbegin, zend, chbegin, chend)`

`ImageInput.read_native_deep_image(subimage=0, miplevel=0)`

Read a collection of scanlines, tiles, or an entire image of “deep” pixel data from the specified subimage and MIP level. The begin/end coordinates are all integer values. The value returned will be a `DeepData` if the read succeeds, or `None` if the read fails.

These methods are guaranteed to be thread-safe against simultaneous calls to any of the other other `read_native` calls that take an explicit subimage/miplevel.

`ImageInput.get_thumbnail(subimage: int = 0) → ImageBuf`

Retrieve an `ImageBuf` containing reduced-resolution (“thumbnail”) version of the image. If no thumbnail could be retrieved, an empty `ImageBuf` will be returned.

`ImageInput.geterror(clear=True)`

Retrieves the error message from the latest failed operation on an `ImageInput`.

Example:

```

input = ImageInput.open (filename)
if not input :
    print ("Open error:", oiio.geterror())
    # N.B. error on open must be retrieved with the global geterror(),
    # since there is no ImageInput object!
else :
    pixels = input.read_image (oiio.FLOAT)
    if not pixels :
        print ("Read_image error:", input.geterror())
    input.close ()

```

11.6.1 Example: Reading pixel values from a file to find min/max

```
#!/usr/bin/env python
import OpenImageIO as oiio

def find_min_max (filename) :
    input = ImageInput.open (filename)
    if not input :
        print ('Could not open "' + filename + '"')
        print ("\tError: ", oiio.geterror())
        return
    spec = input.spec()
    nchans = spec.nchannels
    pixels = input.read_image()
    if not pixels :
        print ("Could not read:", input.geterror())
        return
    input.close()    # we're done with the file at this point
    minval = pixels[0][0]    # initialize to the first pixel value
    maxval = pixels[0][0]
    for y in range(spec.height) :
        for x in range(spec.width) :
            p = pixels[y][x]
            for c in range(nchans) :
                if p[c] < minval[c] :
                    minval[c] = p[c]
                if p[c] > maxval[c] :
                    maxval[c] = p[c]
    print ("Min values per channel were", minval)
    print ("Max values per channel were", maxval)
```

11.7 ImageOutput

See Chapter *ImageOutput: Writing Images* for detailed explanations of the C++ ImageOutput class APIs. The Python APIs are very similar.

`ImageOutput.create(name, plugin_searchpath="")`

Create a new ImageOutput capable of writing the named file format (which may also be a file name, with the type deduced from the extension). There is an optional parameter giving an colon-separated search path for finding ImageOutput plugins. The function returns an ImageOutput object, or None upon error (in which case, `OpenImageIO.geterror()` may be used to retrieve the error message).

Example:

```
import OpenImageIO as oiio
output = ImageOutput.create ("myfile.tif")
if not output :
    print ("Error:", oiio.geterror())
```

ImageOutput.format_name()

The file format name of a created ImageOutput, as a string.

Example:

```
output = ImageOutput.create (filename)
if output :
    print ("Created output", filename, "as a", output.format_name())
```

ImageOutput.supports(feature)

For a created ImageOutput, returns True if the file format supports the named feature (such as “tiles”, “mipmap”, etc., see Section *ImageOutput Class Reference* for the full list), or False if this file format does not support the feature.

Example:

```
output = ImageOutput.create (filename)
if output :
    print (output.format_name(), "supports...")
    print ("tiles?", output.supports("tiles"))
    print ("multi-image?", output.supports("multiimage"))
    print ("MIP maps?", output.supports("mipmap"))
    print ("per-channel formats?", output.supports("channelformats"))
```

ImageOutput.open(filename, spec, mode='Create')

Opens the named output file, with an ImageSpec describing the image to be output. The mode may be one of “Create”, “AppendSubimage”, or “AppendMIPLevel”. See Section *ImageOutput Class Reference* for details. Returns True upon success, False upon failure (error messages retrieved via ImageOutput.geterror().)

Returns

True for success, False for failure.

Example:

```
output = ImageOutput.create (filename)
if not output :
    print ("Error:", oiio.geterror())
spec = ImageSpec (640, 480, 3, "uint8")
ok = output.open (filename, spec)
if not ok :
    print ("Could not open", filename, ":", output.geterror())
```

ImageOutput.open(filename, (imagespec, ...))

This variety of open() is used specifically for multi-subimage files. A tuple of ImageSpec objects is passed, one for each subimage that will be written to the file. After each subimage is written, then a regular call to open(name, newspec, AppendSubimage) moves on to the next subimage.

Returns

True for success, False for failure.

ImageOutput.close()

Closes an open output.

Returns

True for success, False for failure.

ImageOutput.spec()

Returns the ImageSpec of the currently-open output image.

ImageOutput.write_image(pixels)

Write the currently opened image all at once. The `pixels` parameter should be a Numpy ndarray containing data elements indexed as `[y][x][channel]` for normal 2D images, or for 3D volumetric images, as `[z][y][x][channel]`, in other words, exactly matching the shape of array returned by `ImageInput.read_image()`. (It will also work fine if the array is 1D “flattened” version, as long as it contains the correct total number of values.) The data type is deduced from the contents of the array itself. Returns `True` upon success, `False` upon failure.

Example:

```
# This example reads a scanline file, then converts it to tiled
# and writes to the same name.

input = ImageInput.open (filename)
spec = input.spec ()
pixels = input.read_image ()
input.close ()

output = ImageOutput.create (filename)
if output.supports("tiled") :
    spec.tile_width = 64
    spec.tile_height = 64
    output.open (filename, spec)
    output.write_image (pixels)
    output.close ()
```

ImageOutput.write_scanline(y, z, pixels)**ImageOutput.write_scanlines(ybegin, yend, z, pixels)**

Write one or many scanlines to the currently open file. Returns `True` upon success, `False` upon failure.

The `pixels` parameter should be a Numpy ndarray containing data elements indexed as `[x][channel]` for `write_scanline` or as `[y][x][channels]` for `write_scanlines`, exactly matching the shape returned by `ImageInput.read_scanline` or `ImageInput.read_scanlines`. (It will also work fine if the array is 1D “flattened” version, as long as it contains the correct total number of values.)

Example:

```
# Copy a TIFF image to JPEG by copying scanline by scanline.
input = ImageInput.open ("in.tif")
spec = input.spec ()
output = ImageOutput.create ("out.jpg")
output.open (filename, spec)
for z in range(spec.z, spec.z+spec.depth) :
    for y in range(spec.y, spec.y+spec.height) :
        pixels = input.read_scanline (y, z)
        output.write_scanline (y, z, pixels)
output.close ()
input.close ()

# The same example, but copying a whole "plane" of scanlines at a time:
...
for z in range(spec.z, spec.z+spec.depth) :
```

(continues on next page)

(continued from previous page)

```

pixels = input.read_scanlines (spec.y, spec.y+spec.height, z)
output.write_scanlines (spec.y, spec.y+spec.height, z, pixels)
...

```

`ImageOutput.write_tile(x, y, z, pixels)`

`ImageOutput.write_tiles(xbegin, xend, ybegin, yend, zbegin, zend, pixels)`

Write one or many tiles to the currently open file. Returns True upon success, False upon failure.

The `pixels` parameter should be a Numpy ndarray containing data elements indexed as `[y][x][channel]` for normal 2D images, or as `[z][y][x][channels]` 3D volumetric images, exactly matching the shape returned by `ImageInput.read_tile` or `ImageInput.read_tiles`. (It will also work fine if the array is 1D “flattened” version, as long as it contains the correct total number of values.)

Example:

```

input = ImageInput.open (in_filename)
spec = input.spec ()
output = ImageOutput.create (out_filename)
output.open (out_filename, spec)
for z in range(spec.z, spec.z+spec.depth, spec.tile_depth) :
    for y in range(spec.y, spec.y+spec.height, spec.tile_height) :
        for x in range(spec.x, spec.x+spec.width, spec.tile_width) :
            pixels = input.read_tile (x, y, z)
            output.write_tile (x, y, z, pixels)
output.close ()
input.close ()

# The same example, but copying a whole row of of tiles at a time:
...
for z in range(spec.z, spec.z+spec.depth, spec.tile_depth) :
    for y in range(spec.y, spec.y+spec.height, spec.tile_height) :
        pixels = input.read_tiles (spec.x, spec.x+spec.width,
                                   y, y+tile_width, z, z+tile_width)
        output.write_tiles (spec.x, spec.x+spec.width,
                             y, y+tile_width, z, z+tile_width, pixels)
...

```

`ImageOutput.write_deep_scanlinesa(ybegin, yend, z, deepdata)`

`ImageOutput.write_deep_tiles(xbegin, xend, ybegin, yend, zbegin, zend, deepdata)`

`ImageOutput.write_deep_image(deepdata)`

Write a collection of scanlines, tiles, or an entire image of “deep” pixel data. The begin/end coordinates are all integer values, and `deepdata` should be a `DeepData`.

`ImageOutput.set_thumbnail/thumb: ImageBuf)`

Specify a reduced-resolution (“thumbnail”) version of the image, as an `ImageBuf`. Note that many image formats may require the thumbnail to be specified prior to writing the pixels. Return True for success, or False if a thumbnail could not be set.

`ImageOutput.copy_image(imageinput)`

Copy the current image of the open input to the open output. (The reason this may be preferred in some circumstances is that, if input and output were the same kind of input file format, they may have a special efficient technique to copy pixels unaltered, for example by avoiding the decompression/recompression round trip.)

Example:

```

input = ImageInput.open (in_filename)
spec = input.spec ()
output = ImageOutput.create (out_filename)
output.open (filename, spec)
output.copy_image (input)
output.close ()
input.close ()

```

`ImageOutput.geterror(clear=True)`

Retrieves the error message from the latest failed operation on an open file.

Example:

```

output = ImageOutput.create (filename)
if not output :
    print ("Create error:", oiio.geterror())
    # N.B. error on create must be retrieved with the global geterror(),
    # since there is no ImageOutput object!
else :
    ok = output.open (filename, spec)
    if not ok :
        print ("Open error:", output.geterror())
    ok = output.write_image (pixels)
    if not ok :
        print ("Write error:", output.geterror())
    output.close ()

```

11.8 ImageBuf

See Chapter *ImageBuf: Image Buffers* for detailed explanations of the C++ ImageBuf class APIs. The Python APIs are very similar.

ImageBuf()

Construct a new, empty ImageBuf. The ImageBuf is uninitialized and is awaiting a call to `reset()` or `copy()` before it is useful.

ImageBuf(*filename*[, *subimage*, *miplevel*])

Construct a read-only ImageBuf that will read from the named file. Optionally, a specific subimage or MIP level may be specified (defaulting to 0).

Example:

```

import OpenImageIO as oiio
...
buf = ImageBuf ("grid.tif")

```

ImageBuf(*filename*, *subimage*, *miplevel*, *config*)

Construct a read-only ImageBuf that will read from the named file, with an ImageSpec config giving configuration hints.

Example:

```
import OpenImageIO as oiio
...
config = ImageSpec()
config.attribute("oiio:RawColor", 1)
buf = ImageBuf ("grid.tif", 0, 0, config)
```

ImageBuf(*imagespec*, *zero=True*)

Construct a writable ImageBuf of the dimensions and data format specified by an ImageSpec. The pixels will be initialized to black/empty values if *zero* is True, otherwise the pixel values will remain uninitialized.

Example:

```
spec = ImageSpec (640, 480, 3, "float")
buf = ImageBuf (spec)
```

ImageBuf(*data*)

Construct a writable ImageBuf of the dimensions of *data*, which is a NumPy ndarray of values indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel]. The data will be copied into the ImageBuf's internal storage. The NumPy array may be strided for z, y, or x, but must have "contiguous" channel data within each pixel. The pixel data type is also deduced from the contents of the data array.

Note that this Python ImageBuf will contain its own copy of the data, so further changes to the data array will not affect the ImageBuf. This is different from the C++ ImageBuf constructor from a pointer, which will "wrap" the existing user-provided buffer but not make its own copy.

Example:

```
pixels = numpy.zeros ((640, 480, 3), dtype = numpy.float32)
buf = ImageBuf (pixels)
```

ImageBuf.clear()

Resets the ImageBuf to a pristine state identical to that of a freshly constructed ImageBuf using the default constructor.

Example:

```
buf = ImageBuf (...)

# The following two commands are equivalent:
buf = ImageBuf()      # 1 - assign a new blank ImageBuf
buf.clear()           # 2 - clear the existing ImageBuf
```

ImageBuf.reset(*filename*, *subimage=0*, *miplevel=0*, *config=ImageSpec()*)

Restore the ImageBuf to a newly-constructed state, to read from a filename (optionally specifying a subimage, MIP level, and/or a "configuration" ImageSpec).

ImageBuf.reset(*imagespec*, *zero=True*)

Restore the ImageBuf to the newly-constructed state of a writable ImageBuf specified by an ImageSpec. The pixels will be initialized to black/empty if *zero* is True, otherwise the pixel values will remain uninitialized.

ImageBuf.reset(*data*)

Reset the ImageBuf to be sized to the dimensions of *data*, which is a NumPy ndarray of values indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel]. The data will be copied into the ImageBuf's internal storage. The NumPy array may be strided for z, y, or x, but must have

“contiguous” channel data within each pixel. The pixel data type is also deduced from the contents of the data array.

Note that this Python ImageBuf will contain its own copy of the data, so further changes to the data array will not affect the ImageBuf. This is different from the C++ ImageBuf constructor from a pointer, which will “wrap” the existing user-provided buffer but not make its own copy.

`ImageBuf.read(subimage=0, miplevel=0, force=False, convert=oiio.UNKNOWN)`

`ImageBuf.read(subimage, miplevel, chbegin, chend, force, convert)`

Explicitly read the image from the file (of a file-reading ImageBuf), optionally specifying a particular subimage, MIP level, and channel range. If `force` is `True`, will force an allocation of memory and a full read (versus the default of relying on an underlying ImageCache). If `convert` is not the default of `UNKNOWN`, it will force the ImageBuf to convert the image to the specified data format (versus keeping it in the native format or relying on the ImageCache to make a data formatting decision).

Note that a call to `read()` is not necessary — any ImageBuf API call that accesses pixel values will trigger a file read if it has not yet been done. An explicit `read()` is generally only needed to change the subimage or miplevel, or to force an in-buffer read or format conversion.

The `read()` method will return `True` for success, or `False` if the read could not be performed (in which case, a `geterror()` call will retrieve the specific error message).

Example:

```
buf = ImageBuf ("mytexture.exr")
buf.read (0, 2, True)
# That forces an allocation and read of MIP level 2
```

`ImageBuf.init_spec(filename, subimage=0, miplevel=0)`

Explicitly read just the header from a file-reading ImageBuf (if the header has not yet been read), optionally specifying a particular subimage and MIP level. The `init_spec()` method will return `True` for success, or `False` if the read could not be performed (in which case, a `geterror()` call will retrieve the specific error message).

Note that a call to `init_spec()` is not necessary — any ImageBuf API call that accesses the spec will read it automatically if it has not yet been done.

`ImageBuf.write(filename, dtype="", fileformat="")`

Write the contents of the ImageBuf to the named file. Optionally, `dtype` can override the pixel data type (by default, the pixel data type of the buffer), and `fileformat` can specify a particular file format to use (by default, it will infer it from the extension of the file name).

Example:

```
# No-frills conversion of a TIFF file to JPEG
buf = ImageBuf ("in.tif")
buf.write ("out.jpg")

# Convert to uint16 TIFF
buf = ImageBuf ("in.exr")
buf.write ("out.tif", "uint16")
```

`ImageBuf.write(imageoutput)`

Write the contents of the ImageBuf as the next subimage to an open ImageOutput.

Example:

```
buf = ImageBuf (...) # Existing ImageBuf

out = ImageOutput.create("out.exr")
out.open ("out.exr", buf.spec())

buf.write (out)
out.close()
```

ImageBuf.make_writable(*keep_cache_type=False*)

Force the ImageBuf to be writable. That means that if it was previously backed by an ImageCache (storage was IMAGECACHE), it will force a full read so that the whole image is in local memory.

ImageBuf.set_write_format(*format=oiio.UNKNOWN*)

ImageBuf.set_write_tiles(*width=0, height=0, depth=0*)

Override the data format or tile size in a subsequent call to `write()`. The `format` argument to `set_write_format` may be either a single data type description for all channels, or a tuple giving the data type for each channel in order.

Example:

```
# Conversion to a tiled unsigned 16 bit integer file
buf = ImageBuf ("in.tif")
buf.set_write_format ("uint16")
buf.set_write_tiles (64, 64)
buf.write ("out.tif")
```

ImageBuf.spec()

ImageBuf.nativespec()

`ImageBuf.spec()` returns the ImageSpec that describes the contents of the ImageBuf. `ImageBuf.nativespec()` returns an ImageSpec that describes the contents of the file that the ImageBuf was read from (this may differ from `ImageBuf.spec()` due to format conversions, or any changes made to the ImageBuf after the file was read, such as adding metadata).

Handy rule of thumb: `spec()` describes the buffer, `nativespec()` describes the original file it came from.

Example:

```
buf = ImageBuf ("in.tif")
print ("Resolution is", buf.spec().width, "x", buf.spec().height)
```

ImageBuf.specmod()

`ImageBuf.specmod()` provides a reference to the writable ImageSpec inside the ImageBuf. Be very careful! It is safe to modify certain metadata, but if you change the data format or resolution fields, you will get the chaos you deserve.

Example:

```
# Read an image, add a caption metadata, write it back out in place
buf = ImageBuf ("file.tif")
buf.specmod().attribute ("ImageDescription", "my photo")
buf.write ("file.tif")
```

ImageBuf.has_thumbnail

Contains True if the ImageBuf contains thumbnail data, otherwise False.

ImageBuf.clear_thumbnail()

Remove any associated thumbnail from this buffer.

ImageBuf.set_thumbnail(*thumb: ImageBuf*)

Set the thumbnail associated with this buffer to *thumb*.

ImageBuf.thumbnail() → **ImageBuf**

Return an ImageBuf holding any thumbnail associated with this buffer.

ImageBuf.name

The file name of the image (as a string).

ImageBuf.file_format_name

The file format of the image (as a string).

ImageBuf.subimage

ImageBuf.miplevel

ImageBuf.nsubimages

ImageBuf.nmiplevels

Several fields giving information about the current subimage and MIP level, and the total numbers thereof in the file.

ImageBuf.xbegin

ImageBuf.xend

ImageBuf.ybegin

ImageBuf.yend

ImageBuf.zbegin

ImageBuf.zend

The range of valid pixel data window. Remember that the *end* is *one past* the last pixel.

ImageBuf.xmin

ImageBuf.xmax

ImageBuf.ymin

ImageBuf.ymax

ImageBuf.zmin

ImageBuf.zmax

The minimum and maximum (inclusive) coordinates of the pixel data window.

ImageBuf.orientation

ImageBuf.oriented_width

ImageBuf.oriented_height

ImageBuf.oriented_x

ImageBuf.oriented_y

ImageBuf.oriented_full_width

ImageBuf.oriented_full_height

ImageBuf.oriented_full_x

ImageBuf.oriented_full_y

The Orientation field gives the suggested display orientation of the image (see Section *Display hints*).

The other fields are helpers that give the width, height, and origin (as well as “full” or “display” resolution and origin), taking the intended orientation into consideration.

ImageBuf.roi

ImageBuf.roi_full

These fields hold an ROI description of the pixel data window (roi) and the full (a.k.a. “display”) window (roi_full).

Example:

```
buf = ImageBuf ("tahoe.jpg")
print ("Resolution is", buf.roi.width, "x", buf.roi.height)
```

ImageBuf.set_origin(x, y, z=0)

Changes the “origin” of the data pixel data window to the specified coordinates.

Example:

```
# Shift the pixel data so the upper left is at pixel (10, 10)
buf.set_origin (10, 10)
```

ImageBuf.set_full(xbegin, xend, ybegin, yend, zbegin, zend)

Changes the “full” (a.k.a. “display”) window to the specified ROI.

Example:

```
buf.set_full (0, 1024, 0, 768, 0, 1)
```

ImageBuf.pixels_valid

Will be True if the file has already been read and the pixels are valid. (It is always True for writable ImageBuf’s.) There should be few good reasons to access these, since the spec and pixels will be automatically be read when they are needed.

ImageBuf.pixeltype()

Returns a TypeDesc describing the data type of the pixels stored within the ImageBuf.

ImageBuf.copy_metadata(other_imagebuf)

Replaces the metadata (all ImageSpec items, except for the data format and pixel data window size) with the corresponding metadata from the other ImageBuf.

ImageBuf.copy_pixels(other_imagebuf)

Replace the pixels in this ImageBuf with the values from the other ImageBuf.

ImageBuf ImageBuf.copy (format=TypeUnknown)

Return a full copy of this ImageBuf (with optional data format conversion, if format is supplied).

Example:

```
A = ImageBuf("A.tif")

# Make a separate, duplicate copy of A
B = A.copy()

# Make another copy of A, but converting to float pixels
C = A.copy ("float")
```

ImageBuf.copy(other_imagebuf, format=TypeUnknown)

Make this ImageBuf a complete copy of the other ImageBuf. If a format is provided, this will get the specified pixel data type rather than using the same pixel format as the source ImageBuf.

Example:

```
A = ImageBuf("A.tif")

# Make a separate, duplicate copy of A
B = ImageBuf()
B.copy (A)

# Make another copy of A, but converting to float pixels
C = ImageBuf()
C.copy (A, oiio.FLOAT)
```

ImageBuf.swap(*other_imagebuf*)

Swaps the content of this ImageBuf and the other ImageBuf.

Example:

```
A = ImageBuf("A.tif")
B = ImageBuf("B.tif")
A.swap (B)
# Now B contains the "A.tif" image and A contains the "B.tif" image
```

tuple ImageBuf.getpixel (*x*, *y*, *z*=0, *wrap*="black")

Retrieves pixel (*x*,*y*,*z*) from the buffer and return it as a tuple of float values, one for each color channel. The *x*, *y*, *z* values are int pixel coordinates. The optional *wrap* parameter describes what should happen if the coordinates are outside the pixel data window (and may be: "black", "clamp", "periodic", "mirror").

Example:

```
buf = ImageBuf ("tahoe.jpg")
p = buf.getpixel (50, 50)
print (p)

> (0.37, 0.615, 0.97)
```

ImageBuf.getchannel(*x*, *y*, *z*, *channel*, *wrap*='black')

Retrieves just a single channel value from pixel (*x*,*y*,*z*) from the buffer and returns it as a float value. The optional *wrap* parameter describes what should happen if the coordinates are outside the pixel data window (and may be: "black", "clamp", "periodic", "mirror").

Example:

```
buf = ImageBuf ("tahoe.jpg")
green = buf.getchannel (50, 50, 0, 1)
```

ImageBuf.interppixel(*x*, *y*, *wrap*='black')

ImageBuf.interppixel_bicubic(*x*, *y*, *wrap*='black')

Interpolates the image value (bilinearly or bicubically) at coordinates \$(*x*,*y*)\$ and return it as a tuple of float values, one for each color channel. The *x*, *y* values are continuous float coordinates in "pixel space." The optional *wrap* parameter describes what should happen if the coordinates are outside the pixel data window (and may be: "black", "clamp", "periodic", "mirror").

Example:

```
buf = ImageBuf ("tahoe.jpg")
midx = float(buf.xbegin + buf.xend) / 2.0
```

(continues on next page)

(continued from previous page)

```

midy = float(buf.ybegin + buf.yend) / 2.0
p = buf.interpixel (midx, midy)
# Now p is the interpolated value from right in the center of
# the data window

```

ImageBuf.interppixel_NDC(x, y, wrap='black')

ImageBuf.interppixel_bicubic_NDC(x, y, wrap='black')

Interpolates the image value (bilinearly or bicubically) at coordinates (x,y) and return it as a tuple of float values, one for each color channel. The x, y values are continuous, normalized float coordinates in “NDC space,” where (0,0) is the upper left corner of the full (a.k.a. “display”) window, and (1,1) is the lower right corner of the full/display window. The wrap parameter describes what should happen if the coordinates are outside the pixel data window (and may be: “black”, “clamp”, “periodic”, “mirror”).

Example:

```

buf = ImageBuf ("tahoe.jpg")
p = buf.interpixel_NDC (0.5, 0.5)
# Now p is the interpolated value from right in the center of
# the display window

```

ImageBuf.setpixel(x, y, pixel_value)

ImageBuf.setpixel(x, y, z, pixel_value)

Sets pixel (x,y,z) to be the pixel_value, expressed as a tuple of float (one for each color channel).

Example:

```

buf = ImageBuf (ImageSpec (640, 480, 3, oio.UINT8))

# Set the whole image to red (the dumb slow way, but it works):
for y in range(buf.ybegin, buf.yend) :
    for x in range(buf.xbegin, buf.xend) :
        buf.setpixel (x, y, (1.0, 0.0, 0.0))

```

ImageBuf.get_pixels(format=TypeFloat, roi=ROI.All)

Retrieves the rectangle of pixels (and channels) specified by roi from the image and returns them as an array of values with type specified by format.

As with the ImageInput read functions, the return value is a NumPy ndarray containing data elements indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel]). Returns True upon success, False upon failure.

Example:

```

buf = ImageBuf ("tahoe.jpg")
pixels = buf.get_pixels (oio.FLOAT) # no ROI means the whole image

```

ImageBuf.set_pixels(roi, data)

Sets the rectangle of pixels (and channels) specified by roi with values in the data, which is a NumPy ndarray of values indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel]. (It will also work fine if the array is 1D “flattened” version, as long as it contains the correct total number of values.) The data type is deduced from the contents of the array itself.

Example:

```
buf = ImageBuf (...)
pixels = (...)
buf.set_pixels (ROI(), pixels)
```

ImageBuf.has_error

This field will be True if an error has occurred in the ImageBuf.

ImageBuf.geterror(*clear=True*)

Retrieve the error message (and clear the `has_error` flag).

Example:

```
buf = ImageBuf ("in.tif")
buf.read ()    # force a read
if buf.has_error :
    print ("Error reading the file:", buf.geterror())
buf.write ("out.jpg")
if buf.has_error :
    print ("Could not convert the file:", buf.geterror())
```

ImageBuf.pixelindex(*x, y, z, check_range=False*)

Return the index of pixel (x,y,z).

ImageBuf.deep

Will be True if the file contains “deep” pixel data, or False for an ordinary images.

ImageBuf.deep_samples(*x, y, z=0*)

Return the number of deep samples for pixel (x,y,z).

ImageBuf.set_deep_samples(*x, y, z, nsamples*)

Set the number of deep samples for pixel (x,y,z).

ImageBuf.deep_insert_samples(*x, y, z, samplepos, nsamples*)**ImageBuf.deep_erase_samples**(*x, y, z, samplepos, nsamples*)

Insert or erase *nsamples* samples starting at the given position of pixel (x,y,z).

ImageBuf.deep_value(*x, y, z, channel, sample*)**ImageBuf.deep_value_uint**(*x, y, z, channel, sample*)

Return the value of the given deep sample (particular pixel, channel, and sample number) for a channel that is a float or an unsigned integer type, respectively.

ImageBuf.set_deep_value(*x, y, z, channel, sample, value*)**ImageBuf.set_deep_value_uint**(*x, y, z, channel, sample, value*)

Set the value of the given deep sample (particular pixel, channel, and sample number) for a channel that is a float or an unsigned integer type, respectively.

DeepData ImageBuf.deepdata

A reference to the underlying DeepData of the image.

11.9 ImageBufAlgo

The C++ ImageBufAlgo functions are described in detail in Chapter *ImageBufAlgo: Image Processing*. They are also exposed to Python. For the majority of ImageBufAlgo functions, their use in Python is identical to C++; in those cases, we will keep our descriptions of the Python bindings minimal and refer you to Chapter *ImageBufAlgo: Image Processing*, saving the extended descriptions for those functions that differ from the C++ counterparts.

A few things about the parameters of the ImageBufAlgo function calls are identical among the functions, so we will explain once here rather than separately for each function:

- `dst` is an existing ImageBuf, which will be modified (it may be an uninitialized ImageBuf, but it must be an ImageBuf).
- `src` parameter is an initialized ImageBuf, which will not be modified (unless it happens to refer to the same image as `dst`).
- `roi`, if supplied, is an `roi` specifying a region of interest over which to operate. If omitted, the region will be the entire size of the source image(s).
- `nthreads` is the maximum number of threads to use. If not supplied, it defaults to 0, meaning to use as many threads as hardware cores available.

Just as with the C++ ImageBufAlgo functions, if `dst` is an uninitialized ImageBuf, it will be sized to reflect the `roi` (which, in turn, if undefined, will be sized to be the union of the ROI's of the source images).

11.9.1 Pattern generation

ImageBuf ImageBufAlgo.zero (roi, nthreads=0)

ImageBufAlgo.zero(*dst*, *roi*=ROI.All, *nthreads*=0)

Zero out the destination buffer (or a specific region of it).

Example:

```
# Initialize buf to a 640x480 3-channel FLOAT buffer of 0 values
buf = ImageBufAlgo.zero (ROI(0, 640, 0, 480, 0, 1, 0, 3))
```

ImageBuf ImageBufAlgo.fill (values, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.fill (top, bottom, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.fill (topleft, topright, bottomleft, bottomright, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.fill (dst, values, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.fill (dst, top, bottom, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.fill (dst, topleft, topright, bottomleft, bottomright, roi=ROI.All, nthreads=0)

Return a filled float image of size `roi`, or set the the pixels of image `dst` within the ROI to a color or gradient.

Three fill optsins are available: (a) if one color tuple is supplied, the whole ROI will be filled with that constant value, (b) if two color tuples are supplied, a linear gradient will be applied from top to bottom, (c) if four color cuples are supplied, the ROI will be be filled with values bilinearly interpolated from the four corner colors supplied.

Example:

```
# Draw a red rectangle into buf
buf = ImageBuf (ImageSpec(640, 480, 3, TypeDesc.FLOAT)
ImageBufAlgo.fill (buf, (1,0,0), ROI(50, 100, 75, 85))
```

ImageBuf ImageBufAlgo.checker(width, height, depth, color1, color2, xoffset=0, yoffset=0, zoffset=0, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.checker(dst, width, height, depth, color1, color2, xoffset=0, yoffset=0, zoffset=0, roi=ROI.All, nthreads=0)

Return (or copy into dst) a checkerboard pattern. The colors are specified as tuples giving the values for each color channel.

Example:

```
buf = ImageBuf(ImageSpec(640, 480, 3, oiio.UINT8))
ImageBufAlgo.checker (buf, 64, 64, 1, (0.1,0.1,0.1), (0.4,0.4,0.4))
```

ImageBuf ImageBufAlgo.noise (noisetype, A=0.0, B=0.1, mono=False, seed=0, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.noise (dst, noisetype, A=0.0, B=0.1, mono=False, seed=0, roi=ROI.All, nthreads=0)

Return an image of pseudorandom noise, or add pseudorandom noise to the specified region of existing region dst.

For noise type “white” (and its synonym “uniform”), the values are uniformly distributed on the range [A,B] and independently chosen for each pixel. For noise type “blue”, the range will still be uniformly distributed on [A,B] as with “white,” except that the values have better spectral properties for sampling and dithering purposes. For noise “gaussian”, the noise will have a normal distribution with mean A and standard deviation B. For noise “salt”, the value A will be stored in a random set of pixels whose proportion (of the overall image) is B.

For all noise types, choosing different seed values will result in a different pattern. If the mono flag is True, a single noise value will be applied to all channels specified by roi, but if mono is False, a separate noise value will be computed for each channel in the region.

Example:

```
buf = ImageBuf(ImageSpec(640, 480, 3, oiio.UINT8))
ImageBufAlgo.zero (buf)
ImageBufAlgo.noise (buf, 'white', 0.25, 0.75)
```

ImageBuf ImageBufAlgo.bluenoise_image ()

Return a reference to a singleton ImageBuf containing a 4-channel float periodic blue noise image.

Example:

```
buf = ImageBufAlgo.bluenoise_image ()
```

ImageBufAlgo.render_point(dst, x, y, color=(1, 1, 1, 1))

Render a point at pixel (x,y) of dst. The color (if supplied) is a tuple giving the per-channel colors. Return True for success, False for failure.

Example:

```
buf = ImageBuf(ImageSpec (640, 480, 4, oiio.FLOAT))
ImageBufAlgo.render_point (buf, 10, 20, (1,0,0,1))
```

bool ImageBufAlgo.render_line (dst, x1, y1, x2, y2, color=(1,1,1,1), skip_first_point=False)

Render a line from pixel \$(x_1,y_1)\$ to \$(x_2,y_2)\$ into dst. The color (if supplied) is a tuple giving the per-channel colors.

Example:

```
buf = ImageBuf(ImageSpec (640, 480, 4, oiio.FLOAT))
ImageBufAlgo.render_line (buf, 10, 10, 500, 20, (1,0,0,1))
```

bool ImageBufAlgo.render_box (dst, x1, y1, x2, y2, color=(1,1,1,1), filled=False)

Render a filled or unfilled box with corners at pixels \$(x_1,y_1)\$ and \$(x_2,y_2)\$ into dst. The color (if supplied) is a tuple giving the per-channel colors.

Example:

```
buf = ImageBuf(ImageSpec (640, 480, 4, oiio.FLOAT))
ImageBufAlgo.render_box (buf, 150, 100, 240, 180, (0,1,1,1))
ImageBufAlgo.render_box (buf, 100, 50, 180, 140, (0.5, 0.5, 0, 0.5), True)
```

bool ImageBufAlgo.render_text (dst, x, y, text, fontsize=16, fontname="", textcolor=(1,1,1,1), alignx="left", aligny="baseline", shadow=0, roi=ROI.All, nthreads=0)

Render antialiased text into dst. The textcolor (if supplied) is a tuple giving the per-channel colors. Choices for alignx are "left", "right", and "center", and choices for aligny are "baseline", "top", "bottom", and "center".

Example:

```
buf = ImageBuf(ImageSpec (640, 480, 4, oiio.FLOAT))
ImageBufAlgo.render_text (buf, 50, 100, "Hello, world")
ImageBufAlgo.render_text (buf, 100, 200, "Go Big Red!",
                             60, "Arial Bold", (1,0,0,1))
```

ROI ImageBufAlgo.text_size (text, fontsize=16, fontname="")

Compute the size that will be needed for the text as an ROI and return it. The size will not be defined if an error occurred (such as not being a valid font name).

Example:

```
A = ImageBuf(ImageSpec (640, 480, 4, oiio.FLOAT))
Aroi = A.roi
size = ImageBufAlgo.text_size ("Centered", 40, "Courier New")
if size.defined :
    x = Aroi.xbegin + Aroi.width/2 - (size.xbegin + size.width/2)
    y = Aroi.ybegin + Aroi.height/2 - (size.ybegin + size.height/2)
    ImageBufAlgo.render_text (A, x, y, "Centered", 40, "Courier New")

# Note: this was for illustration. An easier way to do this is:
#   render_text (A, x, y, "Centered", 40, "Courier New", alignx="center")
```

11.9.2 Image transformations and data movement

ImageBuf ImageBufAlgo.channels(src, channelorder, newchannelnames=(), shuffle_channel_names=False, nthreads=0)

bool ImageBufAlgo.channels(dst, src, channelorder, newchannelnames=(), shuffle_channel_names=False, nthreads=0)

Return (or store in dst) shuffled channels of src, with channels in the order specified by the tuple channelorder. The length of channelorder specifies the number of channels to copy. Each element in the tuple channelorder may be one of the following:

- **int** : specifies the index (beginning at 0) of the channel to copy.
- **str** : specifies the name of the channel to copy.
- **float** : specifies a constant value to use for that channel.

If newchannelnames is supplied, it is a tuple of new channel names. (See the C++ version for more full explanation.)

Example:

```
# Copy the first 3 channels of an RGBA, drop the alpha
RGBA = ImageBuf("rgba.tif")
RGB = ImageBufAlgo.channels (RGBA, (0,1,2))

# Copy just the alpha channel, making a 1-channel image
Alpha = ImageBufAlgo.channels (RGBA, ("A",))

# Swap the R and B channels
BGR = ImageBufAlgo.channels (RGBA, (2, 1, 0, 3))

# Add an alpha channel with value 1.0 everywhere to an RGB image
RGBA = ImageBufAlgo.channels (RGB, ("R", "G", "B", 1.0),
                              ("R", "G", "B", "A"))
```

ImageBuf ImageBufAlgo.channel_append (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.channel_append (dst, A, B, roi=ROI.All, nthreads=0)

Append the channels of images A and B together into one image.

Example:

```
RGBA = ImageBuf ("rgba.exr")
Z = ImageBuf ("z.exr")
RGBAZ = ImageBufAlgo.channel_append (RGBA, Z)
```

ImageBuf ImageBufAlgo.copy (src, convert=TypeDesc.UNKNOWN, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.copy (dst, src, convert=TypeDesc.UNKNOWN, roi=ROI.All, nthreads=0)

Copy the specified region of pixels of src at the same locations, optionally with the pixel type overridden by convert (if it is not UNKNOWN).

Example:

```
# Copy A's upper left 200x100 region into B
B = ImageBufAlgo.copy (A, ROI(0,200,0,100))
```

ImageBuf ImageBufAlgo.crop (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.crop (dst, src, roi=ROI.All, nthreads=0)

Reset dst to be the specified region of src.

Example:

```
# Set B to be the upper left 200x100 region of A
A = ImageBuf ("a.tif")
B = ImageBufAlgo.crop (A, ROI(0,200,0,100))
```

ImageBuf ImageBufAlgo.cut (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.cut (dst, src, roi=ROI.All, nthreads=0)

Reset dst to be the specified region of src, but moved so that the resulting new image has its pixel data at the image plane origin.

Example:

```
# Set B to be the lower left 200x100 region of A, moved to the origin
A = ImageBuf ("a.tif")
B = ImageBufAlgo.cut (A, ROI(0,200,380,480))
```

bool ImageBufAlgo.paste (dst, xbegin, ybegin, zbegin, chbegin, src, srcroi=ROI.All, nthreads=0)

Copy the specified region of src into dst with the given offset (xbegin, ybegin, zbegin).

Example:

```
# Paste small.exr on top of big.exr at offset (100,100)
Big = ImageBuf ("big.exr")
Small = ImageBuf ("small.exr")
ImageBufAlgo.paste (Big, 100, 100, 0, 0, Small)
```

ImageBuf ImageBufAlgo.rotate90 (src, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.rotate180 (src, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.rotate270 (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.rotate90 (dst, src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.rotate180 (dst, src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.rotate270 (dst, src, roi=ROI.All, nthreads=0)

Copy while rotating the image by a multiple of 90 degrees.

Example:

```
A = ImageBuf ("tahoe.exr")
B = ImageBufAlgo.rotate90 (A)
```

ImageBuf ImageBufAlgo.flip (src, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.flop (src, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.transpose (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.flip (dst, src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.flop (dst, src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.transpose (dst, src, roi=ROI.All, nthreads=0)

Copy while reversing orientation vertically (flip) or horizontally (flop), or diagonally (transpose).

Example:

```
A = ImageBuf ("tahoe.exr")
B = ImageBufAlgo.flip (A)
```

ImageBuf ImageBufAlgo.reorient (src, nthreads=0)

bool ImageBufAlgo.reorient (dst, src, nthreads=0)

Copy src, applying whatever series of rotations, flips, or flops are necessary to transform the pixels into the configuration suggested by the "Orientation" metadata of the image (and the "Orientation" metadata is then set to 1, ordinary orientation).

Example:

```
A = ImageBuf ("tahoe.jpg")
ImageBufAlgo.reorient (A, A)
```

ImageBuf ImageBufAlgo.circular_shift (src, xshift, yshift, zshift=0, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.circular_shift (dst, src, xshift, yshift, zshift=0, roi=ROI.All, nthreads=0)

Copy while circularly shifting by the given amount.

Example:

```
A = ImageBuf ("tahoe.exr")
B = ImageBufAlgo.circular_shift (A, 200, 100)
```

ImageBuf ImageBufAlgo.rotate (src, angle, filtername="", filtersize=0.0, recompute_roi=False, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.rotate (src, angle, center_x, center_y, filtername="", filtersize=0.0, recompute_roi=False, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.rotate (dst, src, angle, filtername="", filtersize=0.0, recompute_roi=False, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.rotate (dst, src, angle, center_x, center_y, filtername="", filtersize=0.0, recompute_roi=False, roi=ROI.All, nthreads=0)

Copy arotated version of the corresponding portion of src. The angle is in radians, with positive values indicating clockwise rotation. If the filter and size are not specified, an appropriate default will be chosen.

Example:

```
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.rotate (Src, math.radians(45.0))
```

ImageBuf ImageBufAlgo.warp (src, M, filtername="", filtersize=0.0, wrap="default", recompute_roi=False, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.warp (dst, src, M, filtername="", filtersize=0.0, wrap="default", recompute_roi=False, roi=ROI.All, nthreads=0)

Compute a warped (transformed) copy of src, with the warp specified by M consisting of 9 floating-point numbers representing a 3x3 transformation matrix. If the filter and size are not specified, an appropriate default will be chosen.

Example:

```
M = (0.7071068, 0.7071068, 0, -0.7071068, 0.7071068, 0, 20, -8.284271, 1)
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.warp (Src, M)
```

```
ImageBuf ImageBufAlgo.st_warp (src, M, filtername="", filtersize=0.0, wrap="default",
recompute_roi=False, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.st_warp (dst, src, M, filtername="", filtersize=0.0, wrap="default",
recompute_roi=False, roi=ROI.All, nthreads=0)
```

Compute a warped (transformed) copy of `src`, with the warp specified by `M` consisting of 9 floating-point numbers representing a 3x3 transformation matrix. If the filter and size are not specified, an appropriate default will be chosen.

Example:

```
# distortion_st.tif is a map where every pixel value contains the 2D
# coordinate of where to copy from.
Distort = ImageBuf("distortion_st.tif")
Src = ImageBuf("tahoe.exr")
Dst = ImageBufAlgo.st_warp(Src, Distort)
```

```
ImageBuf ImageBufAlgo.resize (src, filtername="", filtersize=0.0, roi=ROI.All,
nthreads=0)
```

```
bool ImageBufAlgo.resize (dst, src, filtername="", filtersize=0.0, roi=ROI.All,
nthreads=0)
```

Compute a high-quality resized version of the corresponding portion of `src`. If the filter and size are not specified, an appropriate default will be chosen.

Example:

```
# Resize the image to 640x480, using the default filter
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.resize (Src, roi=ROI(0,640,0,480,0,1,0,3))
```

```
ImageBuf ImageBufAlgo.resample (src, interpolate=True, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.resample (dst, src, interpolate=True, roi=ROI.All, nthreads=0)
```

Set `dst`, over the ROI, to be a low-quality (but fast) resized version of the corresponding portion of `src`, either using a simple “closest pixel” choice or by bilinearly interpolating (depending on `interpolate`).

Example:

```
# Resample quickly to 320x240 to make a low-quality thumbnail
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.resample (Src, roi=ROI(0,640,0,480,0,1,0,3))
```

```
ImageBuf ImageBufAlgo.fit (src, filtername="", filtersize=0.0, fillmode="letterbox",
exact=false, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.fit (dst, src, filtername="", filtersize=0.0, fillmode="letterbox",
exact=false, roi=ROI.All, nthreads=0)
```

Fit `src` into the `roi` while preserving the original aspect ratio, without stretching. If the filter and size are not specified, an appropriate default will be chosen.

Example:

```
# Resize to fit into a max of 640x480, preserving the aspect ratio
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.fit (Src, roi=ROI(0,640,0,480,0,1,0,3))
```

11.9.3 Image arithmetic

ImageBuf ImageBufAlgo.add (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.add (dst, A, B, roi=ROI.All, nthreads=0)

Compute $A + B$. A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.

Example:

```
# Add two images
buf = ImageBufAlgo.add (ImageBuf("a.exr"), ImageBuf("b.exr"))

# Add 0.2 to channels 0-2
ImageBufAlgo.add (buf, buf, (0.2,0.2,0.2,0))
```

ImageBuf ImageBufAlgo.sub (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.sub (dst, A, B, roi=ROI.All, nthreads=0)

Compute $A - B$. A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.

Example:

```
buf = ImageBufAlgo.sub (ImageBuf("a.exr"), ImageBuf("b.exr"))
```

ImageBuf ImageBufAlgo.absdiff (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.absdiff (dst, A, B, roi=ROI.All, nthreads=0)

Compute $\text{abs}(A - B)$. A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.

Example:

```
buf = ImageBufAlgo.absdiff (ImageBuf("a.exr"), ImageBuf("b.exr"))
```

ImageBuf ImageBufAlgo.abs (A, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.abs (dst, A, roi=ROI.All, nthreads=0)

Compute $\text{abs}(A)$. A is an ImageBuf.

Example:

```
buf = ImageBufAlgo.abs (ImageBuf("a.exr"))
```

ImageBuf ImageBufAlgo.mul (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.mul (dst, A, B, roi=ROI.All, nthreads=0)

Compute $A * B$ (channel-by-channel multiplication). A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.

Example:

```
# Multiply the two images
buf = ImageBufAlgo.mul (ImageBuf("a.exr"), ImageBuf("b.exr"))

# Reduce intensity of buf's channels 0-2 by 50%, in place
ImageBufAlgo.mul (buf, buf, (0.5, 0.5, 0.5, 1.0))
```

ImageBuf ImageBufAlgo.div (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.div (dst, A, B, roi=ROI.All, nthreads=0)

Compute A / B (channel-by-channel division), where $x/0$ is defined to be 0. A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.

Example:

```
# Divide a.exr by b.exr
buf = ImageBufAlgo.div (ImageBuf("a.exr"), ImageBuf("b.exr"))

# Reduce intensity of buf's channels 0-2 by 50%, in place
ImageBufAlgo.div (buf, buf, (2.0, 2.0, 2.0, 1.0))
```

ImageBuf ImageBufAlgo.mad (A, B, C, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.mad (dst, A, B, C, roi=ROI.All, nthreads=0)

Compute $A * B + C$ (channel-by-channel multiplication and addition). A, B, and C each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.

Example:

```
# Multiply a and b, then add c
buf = ImageBufAlgo.mad (ImageBuf("a.exr"),
                        (1.0f, 0.5f, 0.25f), ImageBuf("c.exr"))
```

ImageBuf ImageBufAlgo.invert (A, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.invert (dst, A, roi=ROI.All, nthreads=0)

Compute $1-A$ (channel by channel color inverse). A is an ImageBuf.

Example:

```
buf = ImageBufAlgo.invert (ImageBuf("a.exr"))
```

ImageBuf ImageBufAlgo.pow (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.pow (dst, A, B, roi=ROI.All, nthreads=0)

Compute $\text{pow}(A, B)$ (channel-by-channel exponentiation). A is an ImageBuf, and B may be a float (a single power for all channels) or a tuple giving a float for each color channel.

Example:

```
# Linearize a 2.2 gamma-corrected image (channels 0-2 only)
img = ImageBuf ("a.exr")
buf = ImageBufAlgo.pow (img, (2.2, 2.2, 2.2, 1.0))
```

ImageBuf ImageBufAlgo.channel_sum (src, weights=(), roi=ROI.All, nthreads=0)

bool ImageBufAlgo.channel_sum (dst, src, weights=(), roi=ROI.All, nthreads=0)

Converts a multi-channel image into a 1-channel image via a weighted sum of channels. The `weights` is a tuple providing the weight for each channel (if not supplied, all channels will have weight 1.0).

Example:

```
# Compute luminance via a weighted sum of R,G,B
# (assuming Rec709 primaries and a linear scale)
ImageBuf()
weights = (.2126, .7152, .0722)
luma = ImageBufAlgo.channel_sum (ImageBuf("a.exr"), weights)
```

```
ImageBuf ImageBufAlgo.contrast_remap (src, black=0.0, white=1.0, min=0.0, max=1.0,
sthresh=0.0, scontrast=1.0, ROI roi={}, int nthreads=0)
```

```
bool ImageBufAlgo.contrast_remap (ImageBuf &dst, src, black=0.0, white=1.0, min=0.0,
max=1.0, sthresh=0.0, scontrast=1.0, ROI roi={}, int nthreads=0)
```

Return (or copy into dst) pixel values that are a contrast-remap of the corresponding values of the src image, transforming pixel value domain [black, white] to range [min, max], either linearly or with optional application of a smooth sigmoidal remapping (if scontrast != 1.0).

Example:

```
A = ImageBuf('tahoe.tif');

# Simple linear remap that stretches input 0.1 to black, and input
# 0.75 to white.
linstretch = ImageBufAlgo.contrast_remap (A, black=0.1, white=0.75)

# Remapping 0->1 and 1->0 inverts the colors of the image,
# equivalent to ImageBufAlgo.invert().
inverse = ImageBufAlgo.contrast_remap (A, black=1.0, white=0.0)

# Use a sigmoid curve to add contrast but without any hard cutoffs.
# Use a contrast parameter of 5.0.
sigmoid = ImageBufAlgo.contrast_remap (a, contrast=5.0)
```

```
ImageBuf ImageBufAlgo.saturate (src, scale=0.0, firstchannel=0, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.saturate (dst, src, scale=0.0, firstchannel=0, roi=ROI.All, nthreads=0)
```

Copy pixels from src to dst, and scale the saturation of channels firstchannel to firstchannel+2 by the scale factor.

This function was added in OpenImageIO 2.4.

Example:

```
# In-place reduce saturation by 50%
A = ImageBuf ("a.exr")
ImageBufAlgo.saturate (A, A, 0.5)
```

```
ImageBuf ImageBufAlgo.color_map (src, srcchannel, nknots, channels, knots, roi=ROI.All,
nthreads=0)
```

```
ImageBuf ImageBufAlgo.color_map (src, srcchannel, mapname, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.color_map (dst, src, srcchannel, nknots, channels, knots, roi=ROI.All,
nthreads=0)
```

```
bool ImageBufAlgo.color_map (dst, src, srcchannel, mapname, roi=ROI.All, nthreads=0)
```

Return an image (or copy into dst) pixel values determined by applying the color map to the values of src, using either the channel specified by srcchannel, or the luminance of src's RGB if srcchannel is -1.

In the first variant, the values linearly-interpolated color map are given by the tuple knots[nknots*channels].

In the second variant, just the name of a color map is specified. Recognized map names include: “inferno”, “viridis”, “magma”, “plasma”, all of which are perceptually uniform, strictly increasing in luminance, look good when converted to grayscale, and work for people with all types of colorblindness. The “turbo” color map is also nice in most of these ways (except for being strictly increasing in luminance). Also supported are the following color maps that do not have those desirable qualities (and are thus not recommended): “blue-red”, “spectrum”, and “heat”. In all cases, the implied channels is 3.

Example:

```
heatmap = ImageBufAlgo.color_map (ImageBuf("a.jpg"), -1, "inferno")

heatmap = ImageBufAlgo.color_map (ImageBuf("a.jpg"), -1, 3, 3,
                                  (0.25, 0.25, 0.25, 0, 0.5, 0, 1, 0, 0))
```

ImageBuf ImageBufAlgo.max (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.max (dst, A, B, roi=ROI.All, nthreads=0)

Compute per-pixel, per-channel max(A, B), returning the result image. At least one of A and B must be an ImageBuf, the other may also be an ImageBuf, or a float value (for all channels), or a tuple giving a float for each color channel.

Example:

```
# Make an image that for each pixel and channel, is the maximum
# value of that pixel and channel of A and B.
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
maximg = ImageBufAlgo.max (A, B)

# Do an in-place clamp image A so that all values are at least 0
# (thus ensuring that there are no negative values).
ImageBufAlgo.max (A, A, 0.0)
```

ImageBuf ImageBufAlgo.min (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.min (dst, A, B, roi=ROI.All, nthreads=0)

Compute per-pixel, per-channel min(A, B), returning the result image. At least one of A and B must be an ImageBuf, the other may also be an ImageBuf, or a float value (for all channels), or a tuple giving a float for each color channel.

Example:

```
# Make an image that for each pixel and channel, is the minimum
# value of that pixel and channel of A and B.
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
minimg = ImageBufAlgo.min (A, B)

# Do an in-place clamp image A so that the maximum value of each pixel
# is 0.5 (except for alpha, which may be up to 1.0):
ImageBufAlgo.min (A, A, (0.5, 0.5, 0.5, 1.0))
```

ImageBuf ImageBufAlgo.clamp (src, min, max, bool clampalpha01=False, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.clamp (dst, src, min, max, bool clampalpha01=False, roi=ROI.All, nthreads=0)

Copy pixels while clamping between the min and max values. The min and max may either be tuples (one min and max value per channel), or single floats (same value for all channels). Additionally, if clampalpha01 is True, then any alpha channel is clamped to the 0–1 range.

Example:

```
# Clamp image buffer A in-place to the [0,1] range for all channels.
ImageBufAlgo.clamp (A, A, 0.0, 1.0)
```

ImageBuf ImageBufAlgo.maxchan (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.maxchan (dst, src, roi=ROI.All, nthreads=0)

Return a one-channel image where each pixel has the maximum value found in any of the channels of `src` in that corresponding pixel.

This function was added in OpenImageIO 2.3.10.

Example:

```
A = ImageBuf("rgb.exr")
max_of_rgb = ImageBufAlgo.maxchan (A)
```

ImageBuf ImageBufAlgo.minchan (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.minchan (dst, src, roi=ROI.All, nthreads=0)

Return a one-channel image where each pixel has the minimum value found in any of the channels of `src` in that corresponding pixel.

This function was added in OpenImageIO 2.3.10.

Example:

```
A = ImageBuf("rgb.exr")
min_of_rgb = ImageBufAlgo.minchan (A)
```

ImageBuf ImageBufAlgo.rangecompress (src, useluma=False, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.rangecompress (dst, src, useluma=False, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.rangeexpand (src, useluma=False, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.rangeexpand (dst, src, useluma=False, roi=ROI.All, nthreads=0)

Copy from `src`, compressing (logarithmically) or expanding (by the inverse of the compressive transformation) the range of pixel values. Alpha and z channels are copied but not transformed.

If `useluma` is `True`, the luma of the first three channels (presumed to be R, G, and B) are used to compute a single scale factor for all color channels, rather than scaling all channels individually (which could result in a big color shift when performing `rangecompress` and `rangeexpand`).

Example:

```
# Resize the image to 640x480, using a Lanczos3 filter, which
# has negative lobes. To prevent those negative lobes from
# producing ringing or negative pixel values for HDR data,
# do range compression, then resize, then re-expand the range.

# 1. Read the original image
Src = ImageBuf ("tahoeHDR.exr")

# 2. Range compress to a logarithmic scale
Compressed = ImageBufAlgo.rangecompress (Src)

# 3. Now do the resize
roi = ROI (0, 640, 0, 480, 0, 1, 0, Compressed.nchannels)
Dst = ImageBufAlgo.resize (Compressed, "lanczos3", 6.0, roi)

# 4. Expand range to be linear again (operate in-place)
ImageBufAlgo.rangeexpand (Dst, Dst)
```

ImageBuf ImageBufAlgo.over (A, B, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.over (dst, A, B, roi=ROI.All, nthreads=0)

Composite ImageBuf A *over* ImageBuf B.

Example:

```
Comp = ImageBufAlgo.over (ImageBuf("fg.exr"), ImageBuf("bg.exr"))
```

ImageBuf ImageBufAlgo.zover (A, B, bool z_zeroisinf=False, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.zover (dst, A, B, bool z_zeroisinf=False, roi=ROI.All, nthreads=0)

Composite ImageBuf A and ImageBuf B using their respective Z channels to decide which is in front on a pixel-by-pixel basis.

Example:

```
Comp = ImageBufAlgo.zover (ImageBuf("fg.exr"), ImageBuf("bg.exr"))
```

11.9.4 Image comparison and statistics

PixelStats ImageBufAlgo.computePixelStats (src, roi=ROI.All, nthreads=0)

Compute statistics about the ROI of the image src. The PixelStats structure is defined as containing the following data fields: min, max, avg, stddev, nancount, infcount, finitecount, sum, sum2, each of which is a tuple with one value for each channel of the image.

Example:

```
A = ImageBuf("a.exr")
stats = ImageBufAlgo.computePixelStats (A)
print ("  min = ", stats.min)
print ("  max = ", stats.max)
print ("  average = ", stats.avg)
print ("  standard deviation = ", stats.stddev)
print ("  # NaN values = ", stats.nancount)
print ("  # Inf values = ", stats.infcount)
print ("  # finite values = ", stats.finitecount)
```

CompareResults ImageBufAlgo.compare (A, B, failthresh, warnthresh, failrelative=0.0, warnrelative=0.0, roi=ROI.All, nthreads=0)

Numerically compare two ImageBuf's, A and B. The failthresh and warnthresh supply absolute failure and warning difference thresholds, and failrelative and warnrelative supply failure and warning thresholds relative to the values in each image. The return value is a CompareResults object, which is defined as a class having the following members:

```
meanerror, rms_error, PSNR, maxerror  # error statistics
maxx, maxy, maxx, maxc                # pixel of biggest difference
nwarn, nfail                          # number of warnings and failures
error                                  # True if there was an error
```

Example:

```
A = ImageBuf ("a.exr")
B = ImageBuf ("b.exr")
comp = ImageBufAlgo.compare (A, B, 1.0/255.0, 0.0)
if comp.nwarn == 0 and comp.nfail == 0 :
```

(continues on next page)

(continued from previous page)

```

    print ("Images match within tolerance")
else :
    print (comp.nfail, "failures,", comp.nwarn, " warnings.")
    print ("Average error was " , comp.meanerror)
    print ("RMS error was" , comp.rms_error)
    print ("PSNR was" , comp.PSNR)
    print ("largest error was " , comp.maxerror)
    print ("  on pixel", (comp.maxx, comp.maxy, comp.maxz))
    print ("  channel", comp.maxc)

```

tuple ImageBufAlgo.isConstantColor (src, threshold=0.0, roi=ROI.All, nthreads=0)

If all pixels of src within the ROI have the same values (for the subset of channels described by roi), return a tuple giving that color (one float for each channel), otherwise return None.

Example:

```

A = ImageBuf ("a.exr")
color = ImageBufAlgo.isConstantColor (A)
if color != None :
    print ("The image has the same value in all pixels:", color)
else :
    print ("The image is not a solid color.")

```

bool ImageBufAlgo.isConstantChannel (src, channel, val, threshold=0.0, roi=ROI.All, nthreads=0)

Returns True if all pixels of src within the ROI have the given channel value val.

Example:

```

A = ImageBuf ("a.exr")
alpha = A.spec.alpha_channel
if alpha < 0 :
    print ("The image does not have an alpha channel")
elif ImageBufAlgo.isConstantChannel (A, alpha, 1.0) :
    print ("The image has alpha = 1.0 everywhere")
else :
    print ("The image has alpha < 1 in at least one pixel")

```

bool ImageBufAlgo.isMonochrome (src, threshold=0.0, roi=ROI.All, nthreads=0)

Returns True if the image is monochrome within the ROI.

Example:

```

A = ImageBuf ("a.exr")
roi = A.roi
roi.chend = min (3, roi.chend) # only test RGB, not alpha
if ImageBufAlgo.isMonochrome (A, roi) :
    print ("a.exr is really grayscale")

```

ImageBufAlgo.color_range_check (src, low, high, roi=ROI.All, nthreads=0)

Count how many pixels in the src image (within the roi) are outside the value range described by low and hi (which each may be either one value or a tuple with per-channel values for each of roi.chbegin ... roi.chend. The result returned is a tuple containing three values: the number of values less than low, the number of values greater than hi, and the number of values within the range.

Example:

```
A = ImageBuf ("a.exr")
counts = ImageBufAlgo.color_range_check (A, 0.5, 0.75)
print ('{} values < 0.5, {} values > 0.75'.format(counts[0], counts[1]))
```

ROI ImageBufAlgo.nonzero_region (src, roi=ROI.All, nthreads=0)

Returns an ROI that tightly encloses the minimal region within roi that contains all pixels with nonzero values.

Example:

```
A = ImageBuf ("a.exr")
nonzero_roi = ImageBufAlgo.nonzero_region(A)
```

std::string ImageBufAlgo.computePixelHashSHA1 (src, extrainfo = "", roi=ROI.All, blocksize=0, nthreads=0)

Compute the SHA-1 byte hash for all the pixels in the ROI of src.

Example:

```
A = ImageBuf ("a.exr")
hash = ImageBufAlgo.computePixelHashSHA1 (A, blocksize=64)
```

tuple histogram (src, channel=0, bins=256, min=0.0, max=1.0, ignore_empty=False, roi=ROI.All, nthreads=0)

Computes a histogram of the given channel of image src, within the ROI, returning a tuple of length bins containing count of pixels whose value was in each of the equally-sized range bins between min and max. If ignore_empty is True, pixels that are empty (all channels 0 including alpha) will not be counted in the total.

11.9.5 Convolutions

ImageBuf ImageBufAlgo.make_kernel (name, width, height, depth=1.0, normalize=True)}

Create a 1-channel float image of the named kernel and dimensions. If normalize is True, the values will be normalized so that they sum to 1.0.

If depth > 1, a volumetric kernel will be created. Use with caution!

Kernel names can be: “gaussian”, “sharp-gaussian”, “box”, “triangle”, “mitchell”, “blackman-harris”, “b-spline”, “catmull-rom”, “lanczos3”, “cubic”, “keys”, “simon”, “rifman”, “disk”, “binomial”, “laplacian”. Note that “catmull-rom” and “lanczos3” are fixed-size kernels that don’t scale with the width, and are therefore probably less useful in most cases.

Example:

```
K = ImageBufAlgo.make_kernel ("gaussian", 5.0, 5.0)
```

ImageBuf ImageBufAlgo.convolve (src, kernel, normalize=True, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.convolve (dst, src, kernel, normalize=True, roi=ROI.All, nthreads=0)

Replace the given ROI of dst with the convolution of src and a kernel (also an ImageBuf).

Example:

```
# Blur an image with a 5x5 Gaussian kernel
Src = ImageBuf ("tahoe.exr")
```

(continues on next page)

(continued from previous page)

```
K = ImageBufAlgo.make_kernel (K, "gaussian", 5.0, 5.0)
Blurred = ImageBufAlgo.convolve (Src, K)
```

```
ImageBuf ImageBufAlgo.laplacian (src, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.laplacian (dst, src, roi=ROI.All, nthreads=0)
```

Replace the given ROI of dst with the Laplacian of the corresponding part of src.

Example:

```
Src = ImageBuf ("tahoe.exr")
L = ImageBufAlgo.laplacian (Src)
```

```
ImageBuf ImageBufAlgo.fft (src, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.fft (dst, src, roi=ROI.All, nthreads=0)
```

```
ImageBuf ImageBufAlgo.ifft (src, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.ifft (dst, src, roi=ROI.All, nthreads=0)
```

Compute the forward or inverse discrete Fourier Transform.

Example:

```
Src = ImageBuf ("tahoe.exr")

# Take the DFT of the first channel of Src
Freq = ImageBufAlgo.fft (Src)

# At this point, Freq is a 2-channel float image (real, imag)
# Convert it back from frequency domain to a spatial image
Spatial = ImageBufAlgo.ifft (Freq)
```

```
ImageBuf ImageBufAlgo.complex_to_polar (src, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.complex_to_polar (dst, src, roi=ROI.All, nthreads=0)
```

```
ImageBuf ImageBufAlgo.polar_to_complex (src, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.polar_to_complex (dst, src, roi=ROI.All, nthreads=0)
```

Transform a 2-channel image from complex (real, imaginary) representation to polar (amplitude, phase), or vice versa.

Example:

```
Polar = ImageBuf ("polar.exr")

Complex = ImageBufAlgo.polar_to_complex (Polar)

# At this point, Complex is a 2-channel complex image (real, imag)
# Convert it back from frequency domain to a spatial image
Spatial = ImageBufAlgo.ifft (Complex)
```

11.9.6 Image Enhancement / Restoration

ImageBuf ImageBufAlgo.fixNonFinite (src, mode=NONFINITE_BOX3, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.fixNonFinite (dst, src, mode=NONFINITE_BOX3, roi=ROI.All, nthreads=0)

Copy pixel values from src and repair any non-finite (NaN or Inf) pixels.

How the non-finite values are repaired is specified by one of the following modes:

```
OpenImageIO.NONFINITE_NONE
OpenImageIO.NONFINITE_BLACK
OpenImageIO.NONFINITE_BOX3
```

Example:

```
Src = ImageBuf ("tahoe.exr")
ImageBufAlgo.fixNonFinite (Src, Src, OpenImageIO.NONFINITE_BOX3)
```

ImageBuf ImageBufAlgo.fillholes_pushpull (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.fillholes_pushpull (dst, src, roi=ROI.All, nthreads=0)

Copy the specified ROI of src and fill any holes (pixels where alpha < 1) with plausible values using a push-pull technique. The src image must have an alpha channel. The dst image will end up with a copy of src, but will have an alpha of 1.0 everywhere, and any place where the alpha of src was < 1, dst will have a pixel color that is a plausible “filling” of the original alpha hole.

Example:

```
Src = ImageBuf ("holes.exr")
Filled = ImageBufAlgo.fillholes_pushpull (Src)
```

bool ImageBufAlgo.median_filter (dst, src, width=3, height=-1, roi=ROI.All, nthreads=0)

Replace the given ROI of dst with the width x height median filter of the corresponding region of src using the “unsharp mask” technique.

Example:

```
Noisy = ImageBuf ("tahoe.exr")
Clean = ImageBuf ()
ImageBufAlgo.median_filter (Clean, Noisy, 3, 3)
```

ImageBuf ImageBufAlgo.dilate (src, width=3, height=-1, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.dilate (dst, src, width=3, height=-1, roi=ROI.All, nthreads=0)

ImageBuf ImageBufAlgo.erode (src, width=3, height=-1, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.erode (dst, src, width=3, height=-1, roi=ROI.All, nthreads=0) }

Compute a dilated or eroded version of the corresponding region of src.

Example:

```
Source = ImageBuf ("source.tif")
Dilated = ImageBufAlgo.dilate (Source, 3, 3)
```

ImageBuf ImageBufAlgo.unsharp_mask (src, kernel="gaussian", width=3.0, contrast=1.0, threshold=0.0, roi=ROI.All, nthreads=0)

```
bool ImageBufAlgo.unsharp_mask (dst, src, kernel="gaussian", width=3.0, contrast=1.0,
threshold=0.0, roi=ROI.All, nthreads=0)
```

Compute a sharpened version of the corresponding region of `src` using the “unsharp mask” technique.

Example:

```
Blurry = ImageBuf ("tahoe.exr")
Sharp = ImageBufAlgo.unsharp_mask (Blurry, "gaussian", 5.0)
```

11.9.7 Color manipulation

```
ImageBuf ImageBufAlgo.colorconvert (src, fromspace, tospace, unpremult=True,
context_key="", context_value="", colorconfig="", roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.colorconvert (dst, src, fromspace, tospace, unpremult=True,
context_key="", context_value="", colorconfig="", roi=ROI.All, nthreads=0)
```

Apply a color transform to the pixel values.

Example:

```
Src = ImageBuf ("tahoe.jpg")
Dst = ImageBufAlgo.colorconvert (Src, "sRGB", "scene_linear")
```

```
ImageBuf ImageBufAlgo.colormatrixtransform (src, M, unpremult=True, roi=ROI.All,
nthreads=0)
```

```
bool ImageBufAlgo.colormatrixtransform (dst, src, M, unpremult=True, roi=ROI.All,
nthreads=0)
```

NEW in 2.1

Apply a 4x4 matrix color transform to the pixel values. The matrix can be any tuple of 16 float values.

Example:

```
Src = ImageBuf ("tahoe.jpg")
M = ( .8047379, .5058794, -.3106172, 0,
      -.3106172, .8047379, .5058794, 0,
      .5058794, -.3106172, .8047379, 0,
      0, 0, 0, 1)
Dst = ImageBufAlgo.colormatrixtransform (Src, M)
```

```
ImageBuf ImageBufAlgo.ociolook (src, looks, fromspace, tospace, unpremult=True,
inverse=False, context_key="", context_value="", colorconfig="", roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.ociolook (dst, src, looks, fromspace, tospace, unpremult=True,
inverse=False, context_key="", context_value="", colorconfig="", roi=ROI.All, nthreads=0)
```

Apply an OpenColorIO “look” transform to the pixel values.

Example:

```
Src = ImageBuf ("tahoe.jpg")
Dst = ImageBufAlgo.ociolook (Src, "look", "vd8", "lnf",
                             context_key="SHOT", context_value="pe0012")
```

```
ImageBuf ImageBufAlgo.ociodisplay (src, display, view, fromspace="", looks="",
unpremult=True, inverse=False, context_key="", context_value="", colorconfig="", roi=ROI.
All, nthreads=0)
```

```
bool ImageBufAlgo.ociodisplay (dst, src, display, view, fromspace="", looks="",
unpremult=True, inverse=False, context_key="", context_value="", colorconfig="", roi=ROI.
All, nthreads=0)
```

Apply an OpenColorIO “display” transform to the pixel values.

Example:

```
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.ociodisplay (Src, "sRGB", "Film", "lnf",
                                context_key="SHOT", context_value="pe0012")
```

```
ImageBuf ImageBufAlgo.ociofiletransform (src, name, unpremult=True, inverse=False,
colorconfig="", roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.ociofiletransform (dst, src, name, unpremult=True, inverse=False,
colorconfig="", roi=ROI.All, nthreads=0)
```

Apply an OpenColorIO “file” transform to the pixel values. In-place operations (dst and src being the same image) are supported.

Example:

```
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.ociofiletransform (Src, "foottransform.csp")
```

```
ImageBuf ImageBufAlgo.ocionamedtransform (src, name, unpremult=True, inverse=False,
context_key="", context_value="", colorconfig="", roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.ocionamedtransform (dst, src, name, unpremult=True, inverse=False,
context_key="", context_value="", colorconfig="", roi=ROI.All, nthreads=0)
```

Apply an OpenColorIO “named” transform to the pixel values.

Example:

```
Src = ImageBuf ("tahoe.dpx")
Dst = ImageBufAlgo.ocionamedtransform (Src, "log_to_lin",
                                context_key="SHOT", context_value="pe0012")
```

```
ImageBuf ImageBufAlgo.unpremult (src, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.unpremult (dst, src, roi=ROI.All, nthreads=0)
```

```
ImageBuf ImageBufAlgo.premult (src, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.premult (dst, src, roi=ROI.All, nthreads=0)
```

```
ImageBuf ImageBufAlgo.repremult (src, roi=ROI.All, nthreads=0)
```

```
bool ImageBufAlgo.repremult (dst, src, roi=ROI.All, nthreads=0)
```

Copy pixels from src to dst, and un-premultiply, premultiply, or re-premultiply the colors by alpha.

`unpremult` divides colors by alpha, but preserves original color if alpha is 0. `premult` multiplies colors by alpha (even if alpha is 0). `repremult` is the true inverse of `unpremult`, multiplying color by alpha, but preserving color values in the alpha = 0 case.

Example:

```
# Convert in-place from associated alpha to unassociated alpha
A = ImageBuf ("a.exr")
ImageBufAlgo.unpremult (A, A)
```

11.9.8 Import / export

bool ImageBufAlgo.make_texture (mode, input, outputfilename, config=ImageSpec())

Turn an input image (either an ImageBuf or a string giving a filename) into a tiled, MIP-mapped, texture file and write to the file named by (outputfilename). The mode describes what type of texture file we are creating and may be one of the following:

```
OpenImageIO.MakeTxTexture
OpenImageIO.MakeTxEnvLat1
OpenImageIO.MakeTxEnvLat1FromLightProbe
```

The config, if supplied, is an ImageSpec that contains all the information and special instructions for making the texture. The full list of supported configuration options is given in Section *Import / export*.

The return value is True for success, False if errors occurred, in which case the error message will be retrievable from the global `oiio.geterror()`.

Example:

```
# This command line:
#   maketx in.exr --hcomp --filter lanczos3 --opaque-detect \
#       -o texture.exr
# performs the same operations as:

import OpenImageIO as oiio

Input = oiio.ImageBuf ("in.exr")
config = oiio.ImageSpec()
config.attribute ("maketx:highlightcomp", 1)
config.attribute ("maketx:filtername", "lanczos3")
config.attribute ("maketx:opaque_detect", 1)
ok = oiio.ImageBufAlgo.make_texture (oiio.MakeTxTexture, Input,
                                     "texture.exr", config)

if not ok :
    print("error:", oiio.geterror())
```

11.9.9 Functions specific to deep images

ImageBuf ImageBufAlgo.deepen (src, zvalue=1.0, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.deepen (dst, src, zvalue=1.0, roi=ROI.All, nthreads=0)

Convert a flat image to a deep one that has one depth sample per pixel (but no depth samples for the pixels corresponding to those in the source image that have infinite “Z” or that had 0 for all color channels and no “Z” channel).

Example:

```
Deep = ImageBufAlgo.deepen (ImageBuf("az.exr"))
```

ImageBuf ImageBufAlgo.flatten (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.flatten (dst, src, roi=ROI.All, nthreads=0)

Composite the depth samples within each pixel of “deep” ImageBuf src to produce a “flat” ImageBuf.

Example:

```
Flat = ImageBufAlgo.flatten (ImageBuf("deepalpha.exr"))
```

ImageBuf ImageBufAlgo.deep_merge (A, B, occlusion_cull, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.deep_merge (dst, A, B, occlusion_cull, roi=ROI.All, nthreads=0)

Merge the samples of two deep images A and B into a deep result. If `occlusion_cull` is `True`, samples beyond the first opaque sample will be discarded, otherwise they will be kept.

Example:

```
DeepA = ImageBuf("hardsurf.exr")
DeepB = ImageBuf("volume.exr")
Merged = ImageBufAlgo.deep_merge (DeepA, DeepB)
```

ImageBuf ImageBufAlgo.deep_holdout (src, holdout, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.deep_holdout (dst, src, holdout, roi=ROI.All, nthreads=0)

Return the pixels of `src`, but only copying the samples that are closer than the opaque frontier of image `holdout`. That is, `holdout` will serve as a depth holdout mask, but no samples from `holdout` will actually be copied to `dst`.

Example:

```
Img = ImageBuf("image.exr")
Mask = ImageBuf("mask.exr")
Thresholded = ImageBufAlgo.deep_holdout (Img, Mask)
```

11.9.10 Other ImageBufAlgo methods that understand deep images

In addition to the previously described methods that are specific to deep images, the following `ImageBufAlgo` methods (described in their respective sections) work with deep inputs:

```
ImageBufAlgo.add
ImageBufAlgo.channels
ImageBufAlgo.compare
ImageBufAlgo.computePixelStats
ImageBufAlgo.crop
ImageBufAlgo.div
ImageBufAlgo.fixNonFinite
ImageBufAlgo.mul
ImageBufAlgo.nonzero_region
ImageBufAlgo.resample
ImageBufAlgo.sub
```

11.10 Miscellaneous Utilities

In the main OpenImageIO module, there are a number of values and functions that are useful. These correspond to the C++ API functions explained in Section *Global Attributes*, please refer there for details.

openimageio_version

The OpenImageIO version number is an `int`, 10000 for each major version, 100 for each minor version, 1 for each patch. For example, OpenImageIO 1.2.3 would return a value of 10203.

geterror(*clear=True*)

Retrieves the latest global error, as a string.

attribute(*name, typedesc, value*)

attribute(*name, int_value*)

attribute(*name, float_value*)

attribute(*name, str_value*)

Sets a global attribute (see Section *Global Attributes* for details), returning `True` upon success, or `False` if it was not a recognized attribute.

Example:

```
oio.attribute ("threads", 0)
```

getattribute(*name, typedesc*)

get_int_attribute(*name, defaultval=0*)

get_float_attribute(*name, defaultval=0.0*)

get_string_attribute(*name, defaultval=""*)

get_bytes_attribute(*name, defaultval=""*)

Retrieves an attribute value from the named set of global OIIO options. (See Section *Global Attributes*.) The `getattribute()` function returns the value regardless of type, or `None` if the attribute does not exist. The typed variety will only succeed if the attribute is actually of that type specified. Type variety with the type in the name also takes a default value.

For an attribute of type `STRING`, `get_bytes_attribute` in Python3 skips decoding the underlying C string as UTF-8 and returns a bytes object containing the raw byte string.

Example:

```
formats = oio.get_string_attribute ("format_list")
```

is_imageio_format_name(*name*)

Returns `True` if *name* is the name of a known and supported file format, `False` if it is not.

Example:

```
>>> print (oio.is_imageio_format_name('tiff'))
True
>>> print (oio.is_imageio_format_name('Bob'))
False
```

11.11 Python Recipes

This section illustrates the Python syntax for doing many common image operations from Python scripts, but that aren't already given as examples in the earlier function descriptions. All example code fragments assume the following boilerplate:

```
#!/usr/bin/env python

import OpenImageIO as oiio
from OpenImageIO import ImageBuf, ImageSpec, ImageBufAlgo
```

Subroutine to create a constant-colored image

```
# Create an ImageBuf holding a n image of constant color, given the
# resolution, data format (defaulting to UINT8), fill value, and image
# origin.
def make_constimage (xres, yres, chans=3, format=oiio.UINT8, value=(0,0,0),
                    xoffset=0, yoffset=0) :
    spec = ImageSpec (xres,yres,chans,format)
    spec.x = xoffset
    spec.y = yoffset
    b = ImageBuf (spec)
    oiio.ImageBufAlgo.fill (b, value)
    return b
```

The image is returned as an ImageBuf, then up to the caller what to do with it next.

Subroutine to save an image to disk, printing errors

```
# Save an ImageBuf to a given file name, with optional forced image format
# and error handling.
def write_image (image, filename, format=oiio.UNKNOWN) :
    if not image.has_error :
        image.write (filename, format)
    if image.has_error :
        print ("Error writing", filename, ":", image.geterror())
```

Converting between file formats

```
img = ImageBuf ("input.png")
write_image (img, "output.tif")
```

Comparing two images and writing a difference image

```
A = ImageBuf ("A.tif")
B = ImageBuf ("B.tif")
compresulsts = ImageBufAlgo.compare (A, B, 1.0e-6, 1.0e-6)
if compresulsts.nfail > 0 :
    print ("Images did not match, writing difference image diff.tif")
    diff = ImageBufAlgo.absdiff (A, B)
    image_write (diff, "diff.tif")
```

Changing the data format or bit depth

```
img = ImageBuf ("input.exr")
# presume that it's a "half" OpenEXR file
# write it back out as a "float" file:
write_image (img, "output.exr", oio.FLOAT)
```

Changing the compression

The following command converts writes a TIFF file, specifically using LZW compression:

```
img = ImageBuf ("in.tif")
img.specmod().attribute ("compression", "lzw")
write_image (img, "compressed.tif")
```

The following command writes its results as a JPEG file at a compression quality of 50 (pretty severe compression):

```
img = ImageBuf ("big.jpg")
img.specmod().attribute ("quality", 50)
write_image (img, "small.jpg")
```

Converting between scanline and tiled images

```
img = ImageBuf ("scan.tif")
img.set_write_tiles (64, 64)
write_image (img, "tile.tif")

img = ImageBuf ("tile.tif")
```

(continues on next page)

(continued from previous page)

```
img.set_write_tiles (0, 0)
write_image (img, "scan.tif")
```

Adding captions or metadata

```
img = ImageBuf ("foo.jpg")
# Add a caption:
img.specmod().attribute ("ImageDescription", "Hawaii vacation")
# Add keywords:
img.specmod().attribute ("keywords", "volcano,lava")
write_image (img, "foo.jpg")
```

Changing image boundaries

Change the origin of the pixel data window:

```
img = ImageBuf ("in.exr")
img.set_origin (256, 80)
write_image (img, "offset.exr")
```

Change the display window:

```
img = ImageBuf ("in.exr")
img.set_full (16, 1040, 16, 784)
write_image (img, "out.exr")
```

Change the display window to match the data window:

```
img = ImageBuf ("in.exr")
img.set_full (img.roi())
write_image (img, "out.exr")
```

Cut (trim and extract) a 128x128 region whose upper left corner is at location (900,300), moving the result to the origin (0,0) of the image plane and setting the display window to the new pixel data window:

```
img = ImageBuf ("in.exr")
b = ImageBufAlgo.cut (img, oiio.ROI(900,1028,300,428))
write_image (b, "out.exr")
```

Extract just the named channels from a complicated many-channel image, and add an alpha channel that is 1 everywhere

```
img = ImageBuf ("allmyaovs.exr")
b = ImageBufAlgo.channels (img, ("spec.R", "spec.G", "spec.B", 1.0))
write_image (b, "spec.tif")
```

Fade 30% of the way between two images

```
a = ImageBufAlgo.mul (ImageBuf("A.exr"), 0.7)
b = ImageBufAlgo.mul (ImageBuf("B.exr"), 0.3)
fade = ImageBufAlgo.add (a, b)
write_image (fade, "fade.exr")
```

Composite of small foreground over background, with offset

```
fg = ImageBuf ("fg.exr")
fg.set_origin (512, 89)
bg = ImageBuf ("bg.exr")
comp = ImageBufAlgo.over (fg, bg)
write_image (comp, "composite.exr")
```

Write multiple ImageBufs into one multi-subimage file

```
bufs = (...) # Suppose that bufs is a tuple of ImageBuf
specs = (...) # specs is a tuple of the specs that describe them

# Open with intent to write the subimages
out = ImageOutput.create ("multipart.exr")
out.open ("multipart.exr", specs)
for s in range(len(bufs)) :
    if s > 0 :
        out.open ("multipart.exr", specs[s], "AppendSubimage")
    bufs[s].write (out)
out.close ()
```

OIIOTOOL: THE OIIO SWISS ARMY KNIFE

12.1 Overview

The **oiio** program will read images (from any file format for which an ImageInput plugin can be found), perform various operations on them, and write images (in any format for which an ImageOutput plugin can be found).

The **oiio** utility is invoked as follows:

```
oiio args
```

oiio maintains an *image stack*, with the top image in the stack also called the *current image*. The stack begins containing no images.

oiio arguments consist of image names, actions, and flags.

- Image names: When an image name is encountered, that image is pushed on the stack and becomes the new *current image*.
- Actions: Alter the current image (replacing it with the alteration), or in some cases will pull more than one image off the stack (such as the current image and the next item on the stack) and then push a new result image onto the stack.
- Flags: A small number of arguments are non-positional – the order doesn't matter and their effect applies to the entire **oiio** execution.

12.1.1 Argument order matters!

oiio processes actions and inputs *in order*. Thus, the order of operations on the command line is extremely important. For example,

```
oiio in.tif -resize 640x480 -o out.tif
```

has the effect of reading `in.tif` (thus making it the *current image*), resizing it (taking the original off the stack, and placing the resized result back on the stack), and then writing the new current image to the file `out.tif`. Contrast that with the following subtly-incorrect command:

```
oiio in.tif -o out.tif -resize 640x480
```

has the effect of reading `in.tif` (thus making it the *current image*), saving the current image to the file `out.tif` (note that it will be an exact copy of `in.tif`), resizing the current image, and then... exiting. Thus, the resized image is never saved, and `out.tif` will be an unaltered copy of `in.tif`.

The exceptions to this are non-positional flags, which affect the entire **oiio** command regardless of where they appear on the command line.

12.1.2 Optional modifiers

Some arguments stand completely on their own (like `--flip`), others take one or more subsequent command line arguments (like `--resize` or `-o`):

```
oiiotool foo.jpg --flip --resize 640x480 -o out.tif
```

A few arguments take optional modifiers for options that are so rarely-used or confusing that they should not be required arguments. In these cases, they are appended to the command name, after a colon (:), and with a *name=value* format. Multiple optional modifiers can be chained together, with colon separators. As an example:

```
oiiotool in.tif --text:x=400:y=600:color=1,0,0 "Hello" -o out.tif
```

command -----+----- required argument

optional modifiers -----+-----
(separated by ':')

The *value* itself may be a single- or double-quoted string, and this is how you would make a value that itself contains a `:` character (which would otherwise denote the beginning of the next modifier).

12.1.3 Expression evaluation and substitution

oiiotool can perform *expression evaluation and substitution* on command-line arguments. As command-line arguments are needed, they are scanned for containing braces `{ }`. If found, the braces and any text they enclose will be evaluated as an expression and replaced by its result. The contents of an expression may be any of:

- *number*

A numerical value (e.g., 1 or 3.14159).

- *imagename.metadata*

The named metadata of an image.

If there is no metadata whose name matches, the expression will not have any substitution made and an error will be issued.

The *imagename* may be one of:

- TOP : the top or current image;
- BOTTOM : the image at the bottom of the stack;
- IMG[index] : if *index* evaluates to an integer *i*, the *i*-th image on the stack (thus TOP is a synonym for IMG[0], the next image on the stack is IMG[1], ..., and BOTTOM is a synonym for IMG[NIMAGES-1]);
- IMG[name] : an image named by filename or by label name.

Remember that the positions on the stack (including TOP) refer to *at that moment*, with successive commands changing the contents of the top image. If the

The *metadata* may be any of:

- the name of any standard metadata of the specified image (e.g., ImageDescription, or width)
- filename : the name of the file (e.g., foo.tif)
- file_extension : the extension of the file (e.g., tif)

- `full_geom` : the “full” or “display” size
 - `geom` : the pixel data size in the form `640x480+0+0`
 - `nativeformat` : the pixel data type from the file.
 - `MINCOLOR` : the minimum value of each channel over the entire image (channels are comma-separated)
 - `MAXCOLOR` : the maximum value of each channel over the entire image (channels are comma-separated)
 - `AVGCOLOR` : the average pixel value of the image (channels are comma-separated)
 - `NONFINITE_COUNT` : the number of pixel values in the image that are either NaN or Inf values. (Added in OIIO 2.5.10.)
 - `META` : a multi-line string containing the full metadata of the image, similar to what would be printed with `oiiotool -info -v`.
 - `METABRIEF` : a string containing the brief one-line description, similar to what would be printed that with `oiiotool -info`.
 - `METANATIVE` : like `META`, but for the “native” original information from when the file was read from disk.
 - `METANATIVEBRIEF` : like `METABRIEF`, but for the “native” original information from when the file was read from disk.
 - `STATS` : a multi-line string containing the image statistics that would be printed with `oiiotool -stats`.
- *imagename.'metadata'*

If the metadata name is not a “C identifier” (initial letter followed by any number of letter, number, or underscore), it is permissible to use single or double quotes to enclose the metadata name. For example, suppose you want to retrieve metadata named “foo/bar”, you could say

```
{TOP.'foo/bar'}
```

Without the quotes, it might try to retrieve `TOP.foo` (which doesn’t exist) and divide it by `bar`.

- *imagename[metadata]*

Another way to retrieve metadata, but with this notation, the result will be the empty string if the metadata does not exist (that is not an error).

```
{TOP[foo]}
{TOP['bar:baz']}
```

- Arithmetic

Sub-expressions may be joined by `+`, `-`, `*`, `/`, `//`, and `%` for arithmetic operations. (Note that like in Python 3, `/` is floating point division, while `//` signifies integer division.) Parentheses are supported, and standard operator precedence applies.

- Numeric and logical comparisons

Comparisons between numbers may be made with `<`, `<=`, `>`, `>=`, `==`, and `!=`. In each case, the result will be 0 if the comparison is false, 1 if the comparison is true.

The `<=>` operator is a three-way comparison, returning -1, 0, or 1, depending on whether the first operand is less than, equal to, or greater than the second operand.

The `&&` operator has a result of 1 if both the left and right expressions are nonzero, otherwise 0. And `||` has a result of 1 if either the left or right are nonzero, 0 if both evaluate to 0.

- User variables

User variables are set by the `--set` command. A reference to a user variable in an expression will be replaced by the value of the variable.

- Special variables

- `FRAME_NUMBER` : the number of the frame in this iteration of wildcard expansion.
- `FRAME_NUMBER_PAD` : like `FRAME_NUMBER`, but 0-padded based on the value set on the command line by `--framepadding`.
- **`NIMAGES`**
[the number of images currently on the stack. (Added in OIIO 2.4.11.)]

- Functions

- `getattribute(name)` : returns the global attribute that would be retrieved by `OIIO::getattribute(name, ...)`. The name may be enclosed in single or double quotes or be a single unquoted sequence of characters. (Added in OIIO 2.3.)
- `var(name)` : returns the user variable of the give name. (Added in OIIO 2.4.)
- `eq(a,b)` : returns 1 if `a` is equal to `b`, 0 otherwise. (Added in OIIO 2.4.)
- `neq(a,b)` : returns 1 if `a` is not equal to `b`, 0 otherwise. (Added in OIIO 2.4.)
- **`not(val)`**
[returns 1 if `val` is a false value, 0 if `val` evaluates] to a true value. (Added in OIIO 2.4.)]

To illustrate how this works, consider the following command, which trims a four-pixel border from all sides and outputs a new image prefixed with “`cropped_`”, without needing to know the resolution or filename of the original image:

```
oiitool input.exr -cut "{TOP.width-2*4}x{TOP.height-2*4}+{TOP.x+4}+{TOP.y+4}" \
-o cropped_{TOP.filename}
```

If you should come across filenames that contain curly braces (these are very rare, but have been known to happen), you temporarily disable expression evaluation with the `--evaloff` and `--evalon` flags. For example:

```
$ oiitool --info "{weird}.exr"
> oiitool ERROR: expression : syntax error at char 1 of `weird'

$ oiitool --info --evaloff "{weird}.exr"
> {weird.exr}           : 2048 x 1536, 3 channel, half openexr
```

12.1.4 Control flow

Scriptability is provided by the use of control flow statements. The usual programming constructs are supported:

- Conditionals : `--if condition --then commands... --else commands... --endif`
- General looping: `--while condition commands... --endwhile`
- Iteration : `--for variable range commands... --endfor`

The range is a sequence of one to three comma-separated numbers: *begin*, *end*, and *step*; *begin* and *end* (step is assumed to be 1 if *begin* < *end*, or -1 if *begin* > *end*); or just **end* (begin assumed to be 0, step assumed to be 1 or -1, depending on the relationship between *begin* and *end*). As in Python, the range has an “exclusive end” – when the *variable* is equal to *end*, the loop will terminate, without actually running the commands for the *end* value itself.

Section *oiiotool commands for control flow* contains more detailed descriptions of these commands and some examples to more clearly illustrate their behavior.

12.1.5 Frame sequences

It is also possible to have **oiiotool** operate on numbered sequences of images. In effect, this will execute the **oiiotool** command several times, making substitutions to the sequence arguments in turn.

Image sequences are specified by having filename arguments to oiiotool use either a numeric range wildcard (designated such as 1-10# or a printf-like notation 1-10%d), or spelling out a more complex pattern with --frames. For example:

```
oiiotool big.1-3#.tif --resize 100x100 -o small.1-3#.tif
oiiotool big.1-3%04d.tif --resize 100x100 -o small.1-3%04d.tif
oiiotool --frames 1-3 big.#.tif --resize 100x100 -o small.#.tif
oiiotool --frames 1-3 big.%04d.tif --resize 100x100 -o small.%04d.tif
```

Any of those will be the equivalent of having issued the following sequence of commands:

```
oiiotool big.0001.tif --resize 100x100 -o small.0001.tif
oiiotool big.0002.tif --resize 100x100 -o small.0002.tif
oiiotool big.0003.tif --resize 100x100 -o small.0003.tif
```

The frame range may be forwards (1-5) or backwards (5-1), and may give a step size to skip frames (1-5x2 means 1, 3, 5) or take the complement of the step size set (1-5y2 means 2, 4) and may combine subsequences with a comma.

If you are using the # or @ wildcards, then the wildcard characters themselves specify how many digits to pad with leading zeroes, with # indicating 4 digits and @ indicating one digit (these may be combined: #@@ means 6 digits). An optional --framepadding can also be used to override the number of padding digits. For example:

```
oiiotool --framepadding 3 --frames 3,4,10-20x2 blah.#.tif
```

would match blah.003.tif, blah.004.tif, blah.010.tif, blah.012.tif, blah.014.tif, blah.016.tif, blah.018.tif, blah.020.tif.

Alternately, you can use the printf notation, such as:

```
oiiotool --frames 3,4,10-20x2 blah.%03d.tif
```

When using frame ranges, keep in mind that by default, any error (such as an input file not being found) on any frame will exit oiiotool right away. However, the --skip-bad-frames command line option causes an error to skip the rest of the processing for that frame, but try to continue iteration with the next frame.

Two special command line arguments can be used to disable numeric wildcard expansion: --wildcardoff disables numeric wildcard expansion for subsequent command line arguments, until --wildcardon re-enables it for subsequent command line arguments. Turning wildcard expansion off for selected arguments can be helpful if you have arguments that must contain the wildcard characters themselves. For example:

```
oiiotool input.@.tif --wildcardoff --sattrib Caption "lg@openimageio.org" \
--wildcardon -o output.@.tif
```

In this example, the @ characters in the filenames should be expanded into numeric file sequence wildcards, but the @ in the caption (denoting an email address) should not.

12.1.6 Stereo wildcards

oiiotool can also handle image sequences with separate left and right images per frame using **views**. The **%V** wildcard will match the full name of all views and **%v** will match the first character of each view. View names default to “left” and “right”, but may be overridden using the **--views** option. For example:

```
oiiotool --frames 1-5 blah_%V.#.tif
```

would match `blah_left.0001.tif`, `blah_right.0001.tif`, `blah_left.0002.tif`, `blah_right.0002.tif`, `blah_left.0003.tif`, `blah_right.0003.tif`, `blah_left.0004.tif`, `blah_right.0004.tif`, `blah_left.0005.tif`, `blah_right.0005.tif`, and

```
oiiotool --frames 1-5 blah_%v.#.tif
```

would match `blah_l.0001.tif`, `blah_r.0001.tif`, `blah_l.0002.tif`, `blah_r.0002.tif`, `blah_l.0003.tif`, `blah_r.0003.tif`, `blah_l.0004.tif`, `blah_r.0004.tif`, `blah_l.0005.tif`, `blah_r.0005.tif`, but

```
oiiotool --views left --frames 1-5 blah_%v.#.tif
```

would only match `blah_l.0001.tif`, `blah_l.0002.tif`, `blah_l.0003.tif`, `blah_l.0004.tif`, `blah_l.0005.tif`.

12.1.7 Dealing with multi-subimage/multi-part files

Some file formats allow storing multiple images in one file (notably OpenEXR, which calls them “multi-part”). There are some special behaviors to be aware of for multi-subimage files.

Using **oiio**tool for a simple input-to-output copy will preserve all of the subimages (assuming that the output format can accommodate multiple subimages):

```
oiiotool multipart.exr -o another.exr
```

Most **oiio**tool commands by default work on just the *first* subimage of their input, discarding the others. For example:

```
oiiotool multipart.exr --colorconvert lnf aces -o out.exr
```

In this example, only the first subimage in `multipart.exr` will be color transformed and output to `out.exr`. Any other subimages in the input will not be used or copied.

Using the **-a** command tells **oiio**tool to try to preserve all subimages from the inputs and apply all computations to all subimages:

```
oiiotool -a multipart.exr --colorconvert lnf aces -o out.exr
```

Now all subimages of `multipart.exr` will be transformed and output.

But that might not be enough. Perhaps there are some subimages that need the color conversion, and others that do not. Many **oiio**tool commands take an optional modifier **:subimages=...** that can restrict the operation to certain subimages. The argument is a comma-separated list of any of the following: (a) an integer index of a subimage to include, or a minus sign (-) followed by an integer index of a subimage to exclude; (b) the name (as returned by the metadata “oiio:subimagename”) of a subimage to include, or to exclude if preceded by a -; (c) the special string “all”, meaning all subimages. Examples:

```
# Color convert only subimages 0, 3, and 4, leave the rest as-is
oiiotool -a multipart.exr --colorconvert:subimages=0,3,4 lnf aces -o out.exr
```

(continues on next page)

(continued from previous page)

```
# Color convert all subimages EXCEPT the one named "normal"
oiiotool -a multipart.exr --colorconvert:subimages=normal lmf.aces -o out.exr
```

12.2 oiiotool Tutorial / Recipes

This section will give quick examples of common uses of **oiiotool** to get you started. They should be fairly intuitive, but you can read the subsequent sections of this chapter for all the details on every command.

12.2.1 Printing information about images

To print the name, format, resolution, and data type of an image (or many images):

```
oiiotool --info *.tif
```

To also print the full metadata about each input image, use both `--info` and `-v`:

```
oiiotool --info -v *.tif
```

or:

```
oiiotool --info:verbose=1 *.tif
```

To print info about all subimages and/or MIP-map levels of each input image, use the `-a` flag:

```
oiiotool --info -v -a mipmap.exr
```

To print statistics giving the minimum, maximum, average, and standard deviation of each channel of an image, as well as other information about the pixels:

```
oiiotool --stats img_2012.jpg
```

The `--info`, `--stats`, `-v`, and `-a` flags may be used in any combination.

12.2.2 Converting between file formats

It's a snap to convert among image formats supported by OpenImageIO (i.e., for which ImageInput and ImageOutput plugins can be found). The **oiiotool** utility will simply infer the file format from the file extension. The following example converts a PNG image to JPEG:

```
oiiotool lena.png -o lena.jpg
```

The first argument (`lena.png`) is a filename, causing **oiiotool** to read the file and makes it the current image. The `-o` command outputs the current image to the filename specified by the next argument.

Thus, the above command should be read to mean, “Read `lena.png` into the current image, then output the current image as `lena.jpg` (using whatever file format is traditionally associated with the `.jpg` extension).”

12.2.3 Comparing two images

To print a report of the differences between two images of the same resolution:

```
oiiotool old.tif new.tif --diff
```

If you also want to save an image showing just the differences:

```
oiiotool old.tif new.tif --diff --absdiff -o diff.tif
```

This looks complicated, but it's really simple: read `old.tif`, read `new.tif` (pushing `old.tif` down on the image stack), report the differences between them, subtract `new.tif` from `old.tif` and replace them both with the difference image, replace that with its absolute value, then save that image to `diff.tif`.

Sometimes you want to compare images but allow a certain number of small difference, say allowing the comparison to pass as long as no more than 1% of pixels differs by more than 1/255, and as long as no single pixel differs by more than 2/255. You can do this with thresholds:

```
oiiotool old.tif new.tif --fail 0.004 -failpercent 1 --hardfail 0.008 --diff
```

12.2.4 Changing the data format or bit depth

Just use the `-d` option to specify a pixel data format for all subsequent outputs. For example, assuming that `in.tif` uses 16-bit unsigned integer pixels, the following will convert it to an 8-bit unsigned pixels:

```
oiiotool in.tif -d uint8 -o out.tif
```

For formats that support per-channel data formats, you can override the format for one particular channel using `-d CHNAME=TYPE`. For example, assuming `rgbaz.exr` is a float RGBAZ file, and we wish to convert it to be half for RGBA, and float for Z. That can be accomplished with the following command:

```
oiiotool rgbaz.tif -d half -d Z=float -o rgbaz2.exr
```

When converting from a high bit depth data type (like float or half) to a very low bit depth data type (such as uint8), you may notice “banding” artifacts in smooth gradients. To combat this, you can use the `--dither` option to add random dither before the low bit depth quantization, which has the effect of masking the banding:

```
oiiotool half.exr -d uint8 --dither -o out8.tif
```

Note that `--dither` turns dither on for all 8 bit (or fewer) output files. Alternately, you can enable dither for individual outputs using a modifier to `-o` (the value of the dither modifier is the random seed that will be used):

```
oiiotool half.exr -d uint8 -o:dither=1 out8.tif
```

12.2.5 Changing the compression

The following command converts writes a TIFF file, specifically using LZW compression:

```
oiiotool in.tif --compression lzw -o compressed.tif
```

The following command writes its results as a JPEG file at a compression quality of 50 (pretty severe compression), illustrating how some compression methods allow a quality metric to be optionally appended to the name:

```
oiiotool big.jpg --compression jpeg:50 -o small.jpg
```

12.2.6 Converting between scanline and tiled images

Convert a scanline file to a tiled file with 16x16 tiles:

```
oiiotool s.tif --tile 16 16 -o t.tif
```

Convert a tiled file to scanline:

```
oiiotool t.tif --scanline -o s.tif
```

12.2.7 Adding captions or metadata

Add a caption to the metadata:

```
oiiotool foo.jpg --caption "Hawaii vacation" -o bar.jpg
```

Add keywords to the metadata:

```
oiiotool foo.jpg --keyword "volcano,lava" -o bar.jpg
```

Add other arbitrary metadata:

```
oiiotool in.exr --attrib "FStop" 22.0 \
    --attrib "IPTC:City" "Berkeley" -o out.exr

oiiotool in.exr --attrib:type=timecode smpte:TimeCode "11:34:04:00" \
    -o out.exr

oiiotool in.exr --attrib:type=int[4] FaceBBox "140,300,219,460" \
    -o out.exr
```

12.2.8 Changing image boundaries and borders

Change the origin of the pixel data window:

```
oiiotool in.exr --origin +256+80 -o offset.exr
```

Change the display window:

```
oiiotool in.exr --fullsize 1024x768+16+16 -o out.exr
```

Change the display window to match the data window:

```
oiiotool in.exr --fullpixels -o out.exr
```

Crop (trim) an image to a 128x128 region whose upper left corner is at location (900,300), leaving the remaining pixels in their original positions on the image plane (i.e., the resulting image will have origin at 900,300), and retaining its original display window:

```
oiiotool in.exr --crop 128x128+900+300 -o out.exr
```

Cut (trim and extract) a 128x128 region whose upper left corner is at location (900,300), moving the result to the origin (0,0) of the image plane and setting the display window to the new pixel data window:

```
oiiotool in.exr --cut 128x128+900+300 -o out.exr
```

Put a constant-color border around all sides of an image, without needing to know the resolution of the input image:

```
# BW: Border width
BW=40
COLOR=.2,.2,.2,1.0
oiiotool in.tif \
    --pattern constant:color=$COLOR "{TOP.width+2*$BW}x{TOP.height+2*$BW}" "{TOP.
nchannels}" --paste "+$BW+$BW" \
    -o out.tif
```

12.2.9 Scale the values in an image

Reduce the brightness of the R, G, and B channels by 10%, but leave the A channel at its original value:

```
oiiotool original.exr --mulc 0.9,0.9,0.9,1.0 -o out.exr
```

12.2.10 Remove gamma-correction from an image

Convert a gamma-corrected image (with gamma = 2.2) to linear values:

```
oiiotool corrected.exr --powc 2.2,2.2,2.2,1.0 -o linear.exr
```

12.2.11 Resize an image

Resize to a specific resolution:

```
oiiotool original.tif --resize 1024x768 -o specific.tif
```

Resize both dimensions by a known scale factor:

```
oiiotool original.tif --resize 200% -o big.tif
oiiotool original.tif --resize 25% -o small.tif
```

Resize each dimension, independently, by known scale factors:

```
oiiotool original.tif --resize 300%x200% -o big.tif
oiiotool original.tif --resize 100%x25% -o small.tif
```

Resize to a known resolution in one dimension, with the other dimension automatically computed to preserve aspect ratio (just specify 0 as the resolution in the dimension to be automatically computed):

```
oiiotool original.tif --resize 200x0 -o out.tif
oiiotool original.tif --resize 0x1024 -o out.tif
```

Resize to fit into a given resolution, keeping the original aspect ratio and padding with black where necessary to fit into the specified resolution:

```
oiiotool original.tif --fit 640x480 -o fit.tif
```

12.2.12 Color convert an image

This command linearizes a JPEG assumed to be in sRGB, saving as an HDRI OpenEXR file:

```
oiiotool photo.jpg --colorconvert sRGB linear -o output.exr
```

And the other direction:

```
oiiotool render.exr --colorconvert linear sRGB -o fortheweb.png
```

This converts between two named color spaces (presumably defined by your facility's OpenColorIO configuration):

```
oiiotool in.dpx --colorconvert lg10 lnf -o out.exr
```

12.2.13 Grayscale and RGB

Turn a single channel image into a 3-channel gray RGB:

```
oiiotool gray.tif --ch 0,0,0 -o rgb.tif
```

Convert a color image to luminance grayscale:

```
oiiotool RGB.tif --chsum:weight=.2126,.7152,.0722 -o luma.tif
```

12.2.14 Channel reordering and padding

Copy just the color from an RGBA file, truncating the A, yielding RGB only:

```
oiiotool rgba.tif --ch R,G,B -o rgb.tif
```

Zero out the red and green channels:

```
oiiotool rgb.tif --ch R=0,G=0,B -o justblue.tif
```

Swap the red and blue channels from an RGBA image:

```
oiiotool rgba.tif --ch R=B,G,B=R,A -o bgra.tif
```

Extract just the named channels from a many-channel image, as efficiently as possible (avoiding memory and I/O for the unused channels):

```
oiiotool -i:ch=R,G,B manychannels.exr -o rgb.exr
```

Add an alpha channel to an RGB image, setting it to 1.0 everywhere, and naming it “A” so it will be recognized as an alpha channel:

```
oiiotool rgb.tif --ch R,G,B,A=1.0 -o rgba.tif
```

Add an alpha channel to an RGB image, setting it to be the same as the R channel and naming it “A” so it will be recognized as an alpha channel:

```
oiiotool rgb.tif --ch R,G,B,A=R -o rgba.tif
```

Add a z channel to an RGBA image, setting it to 3.0 everywhere, and naming it “Z” so it will be recognized as a depth channel:

```
oiiotool rgba.exr --ch R,G,B,A,Z=3.0 -o rgbaz.exr
```

12.2.15 Copy metadata from one image to another

Suppose you have a (non-OIIO) application that consumes input Exr files and produces output Exr files, but along the way loses crucial metadata from the input files that you want carried along. This command will add all the metadata from the first image to the pixels of the second image:

```
oiiotool metaonly.exr pixelonly.exr --pastemeta -o combined.exr
```

12.2.16 Fade between two images

Fade 30% of the way from A to B:

```
oiiotool A.exr --mulc 0.7 B.exr --mulc 0.3 --add -o fade.exr
```

12.2.17 Simple compositing

Simple “over” composite of aligned foreground and background:

```
oiiotool fg.exr bg.exr --over -o composite.exr
```

Composite of small foreground over background, with offset:

```
oiiotool fg.exr --origin +512+89 bg.exr --over -o composite.exr
```

12.2.18 Creating an animated GIF from still images

Combine several separate JPEG images into an animated GIF with a frame rate of 8 frames per second:

```
oiiotool foo??.jpg --siappendall --attrib FramesPerSecond 10.0 -o anim.gif
```

12.2.19 Frame sequences: composite a sequence of images

Composite foreground images over background images for a series of files with frame numbers in their names:

```
oiiotool fg.1-50%04d.exr bg.1-50%04d.exr --over -o comp.1-50%04d.exr
```

Or:

```
oiiotool --frames 1-50 fg.%04d.exr bg.%04d.exr --over -o comp.%04d.exr
```

12.2.20 Expression example: annotate the image with its caption

This command reads a file, and draws any text in the “ImageDescription” metadata, 30 pixels from the bottom of the image:

```
oiiotool input.exr --text:x=30:y={TOP.height-30} {TOP.ImageDescription} -o out.exr
```

Note that this works without needing to know the caption ahead of time, and will always put the text 30 pixels from the bottom of the image without requiring you to know the resolution.

12.2.21 Contrast enhancement: stretch pixel value range to exactly fit [0-1]

This command reads a file, subtracts the minimum pixel value and then divides by the (new) maximum value, per channel, thus expanding its pixel values to the full [0-1] range:

```
oiiotool input.tif -subc {TOP.MINCOLOR} -divc {TOP.MAXCOLOR} -o out.tif
```

Note that this is a naive way to improve contrast and because each channel is handled independently, it may result in color hue shifts.

12.2.22 Split a multi-image file into separate files

Take a multi-image TIFF file, split into its constituent subimages and output each one to a different file, with names sub0001.tif, sub0002.tif, etc.:

```
oiiotool multi.tif -sisplit -o:all=1 sub%04d.tif
```

12.3 oiiotool commands: general flags

--help

Prints full usage information to the terminal, as well as information about image formats supported, known color spaces, filters, OIIO build options and library dependencies.

--version

Prints the version designation of the OIIO library.

-v

Verbose status messages — print out more information about what **oiiotool** is doing at every step.

-q

Quiet mode — print out less information about what **oiiotool** is doing (only errors).

-n

No saved output — do not save any image files. This is helpful for certain kinds of tests, or in combination with **--runstats** or **--debug**, for getting detailed information about what a command sequence will do and what it costs, but without producing any saved output files.

--no-error-exit

If an error is encountered, try to continue executing any remaining commands, rather than exiting immediately. Use with caution!

--debug

Debug mode — print lots of information about what operations are being performed.

--runstats

Print timing and memory statistics about the work done by **oiiotool**.

--buildinfo

Print information about OIIO build-time options and dependencies. This can be useful when reporting issues.

-a

Performs all operations on all subimages and/or MIPmap levels of each input image. Without **-a**, generally each input image will really only read the top-level MIPmap of the first subimage of the file.

--no-clobber

Sets “no clobber” mode, in which existing images on disk will never be overridden, even if the **-o** command specifies that file.

--threads <n>

Use *n* execution threads if it helps to speed up image operations. The default (also if *n*=0) is to use as many threads as there are cores present in the hardware.

--gpu <n>

EXPERIMENTAL: Enable a GPU or other compute acceleration device, if available.

This was added in OIIO 3.0.

--cache <size>

Causes images to be read through an ImageCache and set the underlying cache size (in MB). See Section [Image-Cache API](#).

--oiioattrib <name> <value>

Adds or replaces a global OpenImageIO attribute with the given *name* to have the specified *value*.

Optional appended modifiers include:

- **type= *typename*** : Specify the metadata type.

If the optional **type=** specifier is used, that provides an explicit type for the metadata. If not provided, it will try to infer the type of the metadata from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as **int** metadata; if it also contains a decimal point, it will be saved as **float** metadata; otherwise, it will be saved as a **string** metadata.

Examples:

```
oiiotool --oiioattrib debug 1 in.jpg -o out.jpg
```

12.4 oiotool commands for control flow

--set <name> <value>

Adds or replaces a “user variable”. User variables may be referenced by name in expression substitution.

Optional appended modifiers include:

- **type= *typename*** : Specify the metadata type.

If the optional **type=** specifier is used, that provides an explicit type for the variable. If not provided, it will try to infer the type from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as **int**; if it also contains a decimal point, it will be saved as a **float**; otherwise, it will be saved as a **string**.

The name of the variable must be in the form of an “identifier” (a sequence of alphanumeric characters and underscores, starting with a letter or underscore).

This command was added in OIIO 2.4.0.

Examples:

```
$ oiotool --set i 42 --echo "i = {i}"
i = 42
```

--if <condition> true-cmds... --endif**--if <condition> true-cmds... --else false-cmds... --endif**

If the *condition* is true, execute *true-cmds*, otherwise execute *false-cmds*.

The *condition* is considered false if it is integer 0 or float 0.0 or the empty string "", or any of the strings off, false, or no (without regard to capitalization). All other values or strings are assumed to be considered “true” for the evaluation of the condition.

Examples:

```
# Read in.exr, and if it only has 3 channels, add an alpha channel
# that is 1.0 everywhere, but if it already has 4 channels, leave
# it alone. Then output the result to out.exr.
$ oiotool in.exr --if "{TOP.nchannels == 3}" --ch ,,,A=1.0 --endif -o rgba.exr
```

--for <variable> <range> *commands*... **--endfor**

Iterate a *variable* over a *range*, executing the *commands* for each iteration. The range may be one, two, or three numbers separated by commas, indicating

- *end* : Iterate from 0 to *end*, incrementing by 1 each iteration (or decrementing, if *end* < 0).
- *begin* , *end* : Iterate from *begin* to *end*, incrementing by 1 each iteration (or decrementing by 1, if *end* < *begin*).
- *begin* , *end* , *step* : Iterate from *begin* to *end*, adding *step* to the value after each iteration.

Note that the *end* value is “exclusive,” that is, the loop will terminate once the value is equal to end, and the loop body will not be executed for the *end* value.

Examples:

```
$ oiotool --for i 5 --echo "i = {i}" --endfor
0
1
2
3
4

$ oiotool --for i 5,10 --echo "i = {i}" --endfor
5
6
7
8
9

$ oiotool --for i 5,10,2 --echo "i = {i}" --endfor
5
7
9

$ oiotool --for i 5,0,-1 --echo "i = {i}" --endfor
5
4
3
2
1
```

--while <condition> *commands*... **--endwhile**

If the *condition* is true, execute *commands*, and keep doing that until the *condition* is false.

The *condition* is considered false if it is integer 0 or float 0.0 or the empty string "", or any of the strings off, false, or no (without regard to capitalization). All other values or strings are assumed to be considered “true” for the evaluation of the condition.

Examples:

```
$ oiiotool -set i 0 --while "{i < 5}" --echo "i = {i}" -set i "{i + 1}" --endwhile
0
1
2
3
4
```

--frames <seq>

--framepadding <n>

Describes the frame range to substitute for the # or %0Nd numeric wildcards. The sequence is a comma-separated list of subsequences; each subsequence is a single frame (e.g., 100), a range of frames (100-150), or a frame range with step (100-150x4 means 100,104,108,...).

The frame padding is the number of digits (with leading zeroes applied) that the frame numbers should have. It defaults to 4.

For example,

```
oiiotool -framepadding 3 -frames 3,4,10-20x2 blah#.tif
```

would match blah.003.tif, blah.004.tif, blah.010.tif, blah.012.tif, blah.014.tif, blah.016.tif, blah.018.tif, blah.020.tif.

--views <name1,name2,...>

Supplies a comma-separated list of view names (substituted for %V and %v). If not supplied, the view list will be left,right.

--skip-bad-frames

When iterating over a frame range, if this option is used, any errors will cease processing that frame, but continue iterating with the next frame (rather than the default behavior of exiting immediately and not even attempting the other frames in the range).

--parallel-frames

When iterating over a frame range or views, if this option is used, the frames will run *concurrently* and not necessarily in any deterministic order.

Running the range of frames in parallel is helpful in cases where (a) there are enough frames in the range to make it be better to parallelize over the range rather than within each operation (rule of thumb: you should probably have at least as many frames to process as cores available); (b) it doesn't matter what order the frames are processed in (e.g., no frames have a dependency on the computed results of earlier frames); and (c) you have enough memory and I/O bandwidth to handle all the parallel jobs (probably equal to the number of cores).

Without the **--parallel-frames** option, the frame range will be executed in increasing numerical order and each frame in the range will run to completion before the next one starts. Multithreading will be used for the individual operations done to each frame. This mode is less efficient if you have more frames than cores available, but it is guaranteed to be safe even if there are order or data dependencies between your frames, and it

This feature was added to OpenImageIO 2.5.1.

--wildcardoff, --wildcardon

These *positional* options turn off (or on) numeric wildcard expansion for subsequent command line arguments. This can be useful in selectively disabling numeric wildcard expansion for a subset of the command line.

--evaloff, --evalon

These *positional* options turn off (or on) expression evaluation (things with { }) for subsequent command line arguments. This can be useful in selectively disabling expression evaluation expansion for a subset of the command line, for example if you actually have filenames containing curly braces.

12.5 oiiotool commands: reading and writing images

The commands described in this section read images, write images, or control the way that subsequent images will be written upon output.

12.5.1 Reading images

<filename>

-i <filename>

If a command-line option is the name of an image file, that file will be read and will become the new *current image*, with the previous current image pushed onto the image stack.

The **-i** command may be used, which allows additional options that control the reading of just that one file.

Optional appended modifiers include:

:now= *int*

If 1, read the image now, before proceeding to the next command.

:autocc= *int*

Enable or disable **--autocc** for this input image (the default is to use the global setting).

:unpremult= *int*

If **autocc** is used for this image, should any color transformation be done on unassociated colors (unmultiplied by alpha). The default is 0.

:info= *int*

Print info about this file (even if the global **--info** was not used) if nonzero. If the value is 2, print full verbose info (like **--info -v**).

:infoformat= *name*

When printing info, the format may be one of: **text** (default) for readable text, or **xml** for an XML description of the image metadata.

:type= *name*

Upon reading, convert the pixel data to the named type. This can override the default behavior of internally storing whatever type is the most precise one found in the file.

:ch= *name...*

Causes the input to read only the specified channels. This is equivalent to following the input with a **--ch** command, except that by integrating into the **-i**, it potentially can avoid the I/O of the unneeded channels.

--iconfig <name> <value>

Sets configuration hint metadata that will apply to the next input file read. Input configuration hint settings are cleared after an image is read, and must be specified separately for every **-i** or image filename to read.

Optional appended modifiers include:

- **type= *typename*** : Specify the metadata type.

If the optional **type=** specifier is used, that provides an explicit type for the metadata. If not provided, it will try to infer the type of the metadata from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as **int** metadata; if it also contains a decimal point, it will be saved as **float** metadata; otherwise, it will be saved as a **string** metadata.

Examples:

```
oiiotool --iconfig "oiio:UnassociatedAlpha" 1 in.png -o out.tif
```

12.5.2 Options that control the reading of all images

These are all non-positional flags that affect how all images are read in the **oiiotool** command.

--autocc

Turns on automatic color space conversion: Every input image file will be immediately converted to a scene-referred linear color space, and every file written will be first transformed to an appropriate output color space based on the filename or type. Additionally, if the name of an output file contains a color space and that color space is associated with a particular data format, it will output that data format (akin to **-d**).

The rules for deducing color spaces are as follows, in order of priority:

1. If the filename (input or output) contains as a substring the name of a color space from the current OpenColorIO configuration, that will be assumed to be the color space of input data (or be the requested color space for output).
2. For input files, if the ImageInput set the "oiio:ColorSpace" metadata, it will be honored if the filename did not override it.
3. When outputting to JPEG files, assume that sRGB is the desired output color space (since JPEG requires sRGB), but still this only occurs if the filename does not specify something different.

If the implied color transformation is unknown (for example, involving a color space that is not recognized), a warning will be printed, but the rest of **oiiotool** processing will proceed (but without having transformed the colors of the image).

Optional appended modifiers include:

:unpremult=*int*

If nonzero, when **autocc** is performed on an image containing an alpha channel, the image will first be unpremultiplied by alpha, then color transformed, then re-premultiplied by alpha, so that the color transformation is done with unassociated color values. The default is 0, meaning that the color transformation will be done directly on the associated color values.

Example:

If the input file **in_lg10.dpx** is in the **lg10** color space, and you want to read it in, brighten the RGB uniformly by 10% (in a linear space, of course), and then save it as a 16 bit integer TIFF file encoded in the **vd16** color space, you could specify the conversions explicitly:

```
oiiotool in_lg10.dpx --colorconvert lg10 linear \
--mulc 1.1,1.1,1.1,1.0 -colorconvert linear vd16 \
-d uint16 -o out_vd16.tif
```

or rely on the naming convention matching the OCIO color space names and use automatic conversion:

```
oiiotool --autocc in_lg10.dpx --mulc 1.1 -o out_vd16.tif
```

--autopremult (default), **-no-autopremult**

By default, OpenImageIO's format readers convert any "unassociated alpha" (color values that are not "premultiplied" by alpha) to the usual associated/premultiplied convention. If the **--no-autopremult** flag is found, subsequent inputs will not do this premultiplication. It can be turned on again via **--autopremult**.

--autoorient

Automatically do the equivalent of **--reorient** on every image as it is read in, if it has a nonstandard orientation. This is generally a good idea to use if you are using **oiio** to combine images that may have different orientations.

--native

Normally, all images read by **oiio** are automatically converted to **float** pixels for internal storage (because any subsequent image processing is usually much faster and more accurate when done on floating-point values), and also if the **--cache** option is used, the reading and storage of images will be mediated through an **ImageCache**.

The **--native** option causes input images to be stored internally in their native pixel data type of the file rather than converted to float. Also, even if the **--cache** option is used, reads will bypass the **ImageCache** (reading directly into an **ImageBuf**) if the pixel data type is not one of the types that is supported internally by **ImageCache** (**UINT8**, **uint16**, **half**, and **float**).

There are three use cases where **--native** might be very helpful: (a) If you are using **oiio** merely for file format or data format conversion, with no actual image processing math performed on the pixel values – in that case, you might save time and memory by avoiding the conversion to **float**. (b) If you are reading exceptionally large images that have smaller data types than **float** (for example, **uint8** pixels), and the only way to make the images fit in memory are to store them as **uint8** rather than converting to float (which takes 4 times as much space in memory). (c) If you know the file has unusual pixel data types that might lose precision if converted to **float** (for example, if you have images with **uint32** or **double** pixels).

--autotile <tilesize>

For the underlying **ImageCache**, turn on auto-tiling with the given tile size. Setting *tilesize* to 0 turns off auto-tiling (the default is off). If auto-tiling is turned on, The **ImageCache** “autoscanline” feature will also be enabled. See Section *ImageCache API* for details.

--missingfile <value>

Determines the behavior when an input file is not found, and no file of that name exists at all. An error is always printed and the **oiio** program always has an error-indicating exit code. But how it proceeds with the rest of the commands may vary depending on the option value:

- **error** : (default) Consider it a full error for that frame iteration.
- **black** : After the error is printed, try to continue with the rest of the command, substituting an opaque black image for the missing file.
- **checker**
[After the error is printed, try to continue with the rest] of the command, substituting a checkerboard image for the missing file.

Note that the resolution, channels, and format (but not arbitrary metadata) of the missing file substitution image will be the same as the first image that was successfully read. If the first image requested is missing (thus, nothing had been successfully read when the missing image is needed), it will be HD resolution, 1920x1080, RGBA.

--info

Print metadata information about each input image as it is read. If verbose mode is turned on (**-v**), all the metadata for the image is printed. If verbose mode is not turned on, only the resolution and data format are printed.

Optional appended modifiers include:

- **format=name** : The format name may be one of: **text** (default) for readable text, or **xml** for an XML description of the image metadata.
- **verbose=1** : If nonzero, the information will contain all metadata, not just the minimal amount.

Note that this is a non-positional flag that will cause metadata to be printed for every input file. There is a separate `--printinfo` action that immediately prints metadata about the current image at the top of the stack (see *oiitool commands that print information about the current image*).

--metamatch <regex>, --no-metamatch <regex>

Regular expressions to restrict which metadata are output when using `oiitool --info -v`. The `--metamatch` expression causes only metadata whose name matches to print; non-matches are not output. The `--no-metamatch` expression causes metadata whose name matches to be suppressed; others (non-matches) are printed. It is not advised to use both of these options at the same time (probably nothing bad will happen, but it's hard to reason about the behavior in that case).

--stats

Print detailed statistical information about each input image as it is read.

Note that this is a non-positional flag that will cause statistics to be printed for every input file. There is a separate `--printstats` action that immediately prints statistics about the current image at the top of the stack (see *oiitool commands that print information about the current image*).

--hash

Print the SHA-1 hash of the pixels of each input image as it is read.

--dumpdata

Print to the console the numerical values of every pixel, for each input image as it is read.

Optional appended modifiers include:

- `C= name` : If present, will cause the output of the data to be in the correct syntax of declaring a C array with the given name. (This was added in OpenImageIO v2.3.9.)
- `empty= verbose` : If 0, will cause deep images to skip printing of information about pixels with no samples.

Examples:

```
$ oiitool --dumpdata image.exr
image.exr      : 256 x 256, 4 channel, float openexr
  Pixel (0, 0): 0.517036676 0.261921108 0.017822538 0.912108004
  Pixel (1, 0): 0.653315008 0.527794302 0.359594107 0.277836263
  ...

$ oiitool --dumpdata:C=foo image.exr
// image.exr    : 256 x 256, 4 channel, float openexr
float foo[256][256][4] =
{
  /* (0, 0): */ { 0.517036676, 0.261921108, 0.017822538, 0.912108004 },
  /* (1, 0): */ { 0.653315008, 0.527794302, 0.359594107, 0.277836263 },
  ...
};
```

12.5.3 Writing images

-o <filename>

Outputs the current image to the named file. This does not remove the current image from the image stack, it merely saves a copy of it.

Optional appended modifiers include:

:type= *name*

Set the pixel data type (like **-d**) for this output image (e.g., `uint8`, `uint16`, `half`, `float`, etc.).

:bits= *int*

Set the bits per pixel (if nonstandard for the datatype) for this output image.

:dither= *int*

Turn dither on or off for this output. When writing floating point data to an 8 bit or less data type in the file, dither can reduce banding artifacts. (default: 0)

:autocc= *int*

Enable or disable **--autocc** for this output image (the default is to use the global setting).

:unpremult= *int*

If autocc is used for this image, should any color transformation be done on unassociated colors (unmultiplied by alpha). The default is 0.

:autocrop= *int*

Enable or disable autocrop for this output image.

:autotrim= *int*

Enable or disable **--autotrim** for this output image.

:separate= *int*, contig= *int*

Set separate or contiguous planar configuration for this output.

:fileformatname= *string*

Specify the desired output file format, overriding any guess based on file name extension.

:scanline= *int*

If nonzero, force scanline output.

:tile= *int* x *int*

Force tiling with given size.

:all= *n*

Output all images currently on the stack using a pattern. See further explanation below.

The **all=n** option causes *all* images on the image stack to be output, with the filename argument used as a pattern assumed to contain a `%d`, which will be substituted with the index of the image (beginning with *n*). For example, to take a multi-image TIFF and extract all the subimages and save them as separate files:

```
oiiotool multi.tif -sisplit -o:all=1 sub%04d.tif
```

This will output the subimages as separate files `sub0001.tif`, `sub0002.tif`, and so on.

-otex <filename>

-oenv <filename>

-obump <filename>

Outputs the current image to the named file, as a MIP-mapped texture or environment map, identical to that which would be output by **maketx** (Chapter [Making Tiled MIP-Map Texture Files With maketx or oiiotool](#)). The advantage of using **oiiotool** rather than **maketx** is simply that you can have a complex **oiiotool** command

line sequence of image operations, culminating in a direct saving of the results as a texture map, rather than saving to a temporary file and then separately invoking `maketx`.

In addition to all the optional arguments of `-o`, optional appended arguments for `-otex`, `-oenv`, and `-obump` also include:

`:wrap= string`
Set the default `$$` and `t` wrap modes of the texture, to one of: `:black`, `clamp`, `periodic`, `mirror`.

`:swrap= string`
Set the default `$$` wrap mode of the texture.

`:twrap= string`
Set the default `t` wrap mode of the texture.

`:resize= int`
If nonzero, resize to a power of 2 before starting to create the MIPmap levels. (default: 0)

`:nomipmap= int`
If nonzero, do not create MIP-map levels at all. (default: 0)

`:updatemode= int`
If nonzero, do not create and overwrite the existing texture if it appears to already match the source pixels. (default: 0)

`:constant_color_detect= int`
Detect images that are entirely one color, and change them to be low resolution. (default: 0)

`:monochrome_detect= int`
Detect monochrome (R=G=B) images and turn them into 1-channel textures. (default: 0)

`:opaque_detect= int`
Detect opaque (A=1) images and drop the alpha channel from the texture. (default: 0)

`:compute_average= int`
Compute and store the average color of the texture. (default: 1)

`:unpremult= int`
Unpremultiply colors before any per-MIP-level color conversions, and re-premultiply after. (default: 0)

`:incolospace= string`
Specify color space conversion.

`:outcolospace= string`
...

`:highlightcomp= int`
Use highlight compensation for HDR images when resizing for MIP-map levels. (default: 0)

`:sharpen= float`
Additional sharpening factor when resizing for MIP-map levels. (default: 0.0)

`:filter= string`
Specify the filter for MIP-map level resizing. (default: box)

`:prman_metadata= int`
Turn all all options required to make the resulting texture file compatible with PRMan (particular tile sizes, formats, options, and metadata). (default: 0)

`:prman_options= int`
Include the metadata that PRMan's texture system wants. (default: 0)

:bumpformat= *string*

For `-obump` only, specifies the interpretation of 3-channel source images as one of: `height`, `normal`, `auto` (default).

:uvslopes_scale= *float*

For `-obump` only, specifies the amount to scale the bump-map slopes by. (default: 0.0, meaning not to use this feature)

:cdf= *int*

If nonzero, will add to the texture metadata the forward and inverse Gaussian CDF, which can be used by shaders to implement Histogram-Preserving blending. (default: 0)

:cdfsigma= *float*

In conjunction with `cdf=1`, specifies the sigma value to use for the CDF (default: 1.0/6.0).

:cdfbits= *int*

In conjunction with `cdf=1`, specifies the number of bits to use for the size of the CDF table (default: 8, meaning 256 bins).

:handed= *string*

Specifies the handedness of a vector displacement map or normal map when using tangent space coordinates. Valid values are “left” or “right” (default: none).

Examples:

```
oiiotool in.tif -otex out.tx

oiiotool in.jpg --colorconvert sRGB linear -d uint16 -otex out.tx

oiiotool --pattern:checker 512x512 3 -d uint8 -otex:wrap=periodic checker.tx

oiiotool in.exr -otex:highlightcomp=1:sharpen=0.5 out.exr
```

-d <datatype>

-d <channelname>=<datatype>

-d <subimage>.*=<datatype>

-d <subimage>.<channelname>=<datatype>

Attempts to set the pixel data type of all subsequent outputs. If no channel or subimage name is given, sets *all* channels to be the specified data type. If a specific channel is named, then the data type will be overridden for just that channel (multiple `-d` commands may be used). If both a subimage name and channel name are specified, the hint is only for the named channel when encountered in a named subimage. And if the specification is of the form `subimage.*=type`, then all channels of that subimage will be output with the given type.

Valid types are: `uint8`, `sint8`, `uint16`, `sint16`, `half`, `float`, `double`. The types `uint10` and `uint12` may be used to request 10- or 12-bit unsigned integers. If the output file format does not support them, `uint16` will be substituted.

If the `-d` option is not supplied, the output data type will be deduced from the data format of the input files, if possible.

In any case, if the output file type does not support the requested data type, it will instead use whichever supported data type results in the least amount of precision lost.

--scanline

Requests that subsequent output files be scanline-oriented, if scanline orientation is supported by the output file format. By default, the output file will be scanline if the input is scanline, or tiled if the input is tiled.

--tile <x> <y>

Requests that subsequent output files be tiled, with the given $x \times y$ tile size, if tiled images are supported by the output format. By default, the output file will take on the tiledness and tile size of the input file.

--compression <method>**--compression <method:quality>**

Sets the compression method, and optionally a quality setting, for the output image. Each ImageOutput plugin will have its own set of methods that it supports.

Sets the compression method, and optionally a quality setting, for the output image. Each ImageOutput plugin will have its own set of methods that it supports.

--quality <q>

Sets the compression quality, on a 1-100 floating-point scale. This only has an effect if the particular compression method supports a quality metric (as JPEG does).

This is considered deprecated, and in general we now recommend just appending the quality metric to the `--compression name:qual`.

--dither

Turns on *dither* when outputting to 8-bit or less image files (does not affect other data types). This adds just a bit of noise that reduces visible banding artifacts. The dither seed will be selected based on a hash of the output filename, and therefore will be a different random pattern for different files. It only has an effect when outputting to a file of 8 or fewer bits per sample, and only when the data being saved starts off with higher than 8 bit precision.

--planarconfig <config>

Sets the planar configuration of subsequent outputs (if supported by their formats). Valid choices are: `config` for contiguous (or interleaved) packing of channels in the file (e.g., RGBRGBRGB...), `separate` for separate channel planes (e.g., RRRR...GGGG...BBBB...), or `default` for the default choice for the given format. This command will be ignored for output files whose file format does not support the given choice.

--adjust-time

When this flag is present, after writing each output, the resulting file's modification time will be adjusted to match any "DateTime" metadata in the image. After doing this, a directory listing will show file times that match when the original image was created or captured, rather than simply when **oiio** was run. This has no effect on image files that don't contain any "DateTime" metadata.

--noautocrop

For subsequent outputs, do *not* automatically crop images whose formats don't support separate pixel data and full/display windows. Without this, the default is that outputs will be cropped or padded with black as necessary when written to formats that don't support the concepts of pixel data windows and full/display windows. This is a non-issue for file formats that support these concepts, such as OpenEXR.

--autotrim

For subsequent outputs, if the output format supports separate pixel data and full/display windows, automatically trim the output so that it writes the minimal data window that contains all the non-zero valued pixels. In other words, trim off any all-black border rows and columns before writing the file.

--metamerge

When this flag is used, most image operations will try to merge the metadata found in all of their source input images into the output. The default (if this is not used) is that image operations with multiple input images will just take metadata from the first source image.

(This was added for OpenImageIO 2.1.)

12.6 oiiotool commands that print information about the current image

--echo <message>

Prints the message to the console, at that point in the left-to-right execution of command line arguments. The message may contain expressions for substitution.

Optional appended modifiers include:

- **newline=n** : The number of newlines to print after the message (default is 1, but 0 will suppress the newline, and a larger number will make more vertical space).

Examples:

```
oiiotool test.tif --resize 256x0 --echo "result is {TOP.width}x{TOP.height}"
```

This will resize the input to be 256 pixels wide and automatically size it vertically to preserve the original aspect ratio, and then print a message to the console revealing the resolution of the resulting image.

--list-formats

Prints the complete list of file formats supported by this build of OpenImageIO, and for each one, the list of file extensions that it presumes are associated with the file format. (Added in OIIO 2.2.13.)

--printinfo

Prints information and all metadata about the current (top) image. This behavior is similar to invoking oiiotool with **--info -v**, but it applies immediately to the current top image, even if it is a “computed” image (whereas **--info** only applies to images as they are read from disk).

Optional appended modifiers include:

- **:allsubimages= int**
If nonzero, stats will be printed about all subimages of the current image. (The default is given by whether or not the **-a** option was used.)
- **:native=1**
Print metadata reflecting the “native” image as it was originally read from disk. This may have a data type, tile size, or other items that differ from the current in-memory representation of the image.
- **:stats=1**
Print statistics about the image (much like the **--stats** command).
- **:verbose=0**
Overrides the default verbosity (1, on) with a less verbose output.

--printstats

Prints detailed statistical information about the current image. This behavior is similar to invoking oiiotool with **--stats**, but it applies immediately to the current top image, even if it is a “computed” image (whereas **--stats** only applies to images as they are read from disk).

Optional appended modifiers include:

- **:window= geom**
If present, restricts the statistics to a rectangular subset of the image. The default, if not present is to print the statistics of the full data window of the image. The rectangle can be specified using either of these image geometry notations:

width x height [+/-] xoffset [+/-] yoffset

xmin,ymin,xmax,ymax

- **:allsubimages= *int***

If nonzero, stats will be printed about all subimages of the current image. (The default is given by whether or not the -a option was used.)

--colorcount *r1,g1,b1,...:r2,g2,b2,...:...*

Given a list of colors separated by colons or semicolons, where each color is a list of comma-separated values (for each channel), examine all pixels of the current image and print a short report of how many pixels matched each of the colors.

Optional appended modifiers include:

- **eps=*r,g,b,...*** : Tolerance for matching colors (default: 0.001 for all channels).

Examples:

```
oiiotool test.tif --colorcount "0.792,0,0,1;0.722,0,0,1"
```

might produce the following output:

```
10290 0.792,0,0,1
11281 0.722,0,0,1
```

Notice that use of double quotes " " around the list of color arguments, in order to make sure that the command shell does not interpret the semicolon (;) as a statement separator. An alternate way to specify multiple colors is to separate them with a colon (:), for example:

```
oiiotool test.tif --colorcount 0.792,0,0,1:0.722,0,0,1
```

Another example:

```
oiiotool test.tif --colorcount:eps=.01,.01,.01,1000 "0.792,0,0,1"
```

This example sets a larger epsilon for the R, G, and B channels (so that, for example, a pixel with value [0.795,0,0] would also match), and by setting the epsilon to 1000 for the alpha channel, it effectively ensures that alpha will not be considered in the matching of pixels to the color value.

--rangecheck *Rlow,Glow,Blow,... Rhi,Bhi,Ghi,...*

Given a two colors (each a comma-separated list of values for each channel), print a count of the number of pixels in the image that has channel values outside the [low,hi] range. Any channels not specified will assume a low of 0.0 and high of 1.0.

Example:

```
oiiotool test.exr --rangecheck 0,0,0 1,1,1
```

might produce the following output:

```
0 < 0,0,0
221 > 1,1,1
65315 within range
```

--diff

--fail <A> **--failpercent** **--hardfail** <C>

--warn <A> **--warnpercent** **--hardwarn** <C>

This command computes the difference of the current image and the next image on the stack, and prints a report of those differences (how many pixels differed, the maximum amount, etc.). This command does not alter the image stack.

The `--fail`, `--failpercent`, and `--hardfail` options set thresholds for **FAILURE**: if more than B % of pixels (on a 0-100 floating point scale) are greater than A different, or if *any* pixels are more than C different. The defaults are to fail if more than 0% (any) pixels differ by more than 0.00001 (1e-6), and C is infinite.

The `--warn`, `--warnpercent`, and `--hardwarn` options set thresholds for **WARNING**: if more than B % of pixels (on a 0-100 floating point scale) are greater than A different, or if *any* pixels are more than C different. The defaults are to warn if more than 0% (any) pixels differ by more than 0.00001 (1e-6), and C is infinite.

`--pdiff`

This command computes the difference of the current image and the next image on the stack using a perceptual metric, and prints whether or not they match according to that metric. This command does not alter the image stack.

12.7 oiiotool commands that change the current image metadata

This section describes **oiiotool** commands that alter the metadata of the current image, but do not alter its pixel values. Only the current (i.e., top of stack) image is affected, not any images further down the stack.

If the `-a` flag has previously been set, these commands apply to all subimages or MIPmap levels of the current top image. Otherwise, they only apply to the highest-resolution MIPmap level of the first subimage of the current top image.

`--attrib <name> <value>`

`--sattrib <name> <value>`

Adds or replaces metadata with the given *name* to have the specified *value*.

Optional appended modifiers include:

`:subimages=indices-or-names`

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*). Only included subimages will have the attribute changed. If subimages are not set, only the first subimage will be changed, or all subimages if the `-a` command line flag was used.

`:type=typename` : Specify the metadata type.

If the optional `type=` specifier is used, that provides an explicit type for the metadata. If not provided, it will try to infer the type of the metadata from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as `int` metadata; if it also contains a decimal point, it will be saved as `float` metadata; otherwise, it will be saved as a `string` metadata.

The `--sattrib` command is equivalent to `--attrib:type=string`.

Examples:

```
# Set the IPTC:City attribute to "Berkeley"
oiiotool in.jpg --attrib "IPTC:City" "Berkeley" -o out.jpg

# Set a name attribute to "0", but force it to be a string
oiiotool in.jpg --attrib:type=string "Name" "0" -o out.jpg

# Another way to force a string attribute using --sattrib:
oiiotool in.jpg --sattrib "Name" "0" -o out.jpg

# Set the worldcam attribute to be a matrix
oiiotool in.exr --attrib:type=matrix worldtocam \
    "1,0,0,0,0,1,0,0,0,0,1,0,2.3,2.1,0,1" -o out.exr
```

(continues on next page)

(continued from previous page)

```
# Set an attribute to be a timecode
oiiotool in.exr --attrib:type=timecode smpte:TimeCode "11:34:04:00" -o out.exr

# Set an attribute in all subimages
oiiotool multipart.exr --attrib:subimages=all "Foo" "bar" -o out.exr

# Set an attribute just in subimages 0 and 3
oiiotool multipart.exr --attrib:subimages=0,3 "Foo" "bar" -o out.exr
```

--caption <text>

Sets the image metadata "ImageDescription". This has no effect if the output image format does not support some kind of title, caption, or description metadata field. Be careful to enclose *text* in quotes if you want your caption to include spaces or certain punctuation!

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*). Only included subimages will have the attribute changed. If subimages are not set, only the first subimage will be changed, or all subimages if the `-a` command line flag was used.

--keyword <text>

Adds a keyword to the image metadata "Keywords". Any existing keywords will be preserved, not replaced, and the new keyword will not be added if it is an exact duplicate of existing keywords. This has no effect if the output image format does not support some kind of keyword field.

Be careful to enclose *text* in quotes if you want your keyword to include spaces or certain punctuation. For image formats that have only a single field for keywords, OpenImageIO will concatenate the keywords, separated by semicolon (;), so don't use semicolons within your keywords.

--clear-keywords

Clears all existing keywords in the current image.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*). Only included subimages will have the attribute changed. If subimages are not set, only the first subimage will be changed, or all subimages if the `-a` command line flag was used.

--history**--no-history****--nosoftwareattrib**

By default, oiiotool writes "OpenImageIO <version>" and a SHA-1 hash of the command line as the "Software" metadata in output images.

The `--history` option appends the full command line arguments and appends that information to the "Image-History" metadata as well. This behavior is "opt-in" because some users may find it undesirable for metadata in the image to potentially reveal any proprietary information that might have been present in the command line arguments.

If the `OPENIMAGEIO_METADATA_HISTORY` environment variable is set to a nonzero integer value, the `--history` option will be enabled by default, but can be disabled on the command line with `--no-history`.

The `--nosoftwareattrib` option prevents even the minimal default information from being written, so that no information about the software is written to any metadata field.

Prior to OpenImageIO 2.5.11, the full information was always written, but could be overridden with `--nosoftwareattrib`. Beginning with 2.5.11, the default changed to only write the software name and version (unless the `OPENIMAGEIO_METADATA_HISTORY` environment variable is set), and require the new `--history` option to cause the command line arguments to be written as metadata.

`--sansattrib`

When set, this edits the command line inserted in the “Software” and “ImageHistory” metadata to omit any verbose `--attrib` and `--sattrib` commands.

`--eraseattrib <pattern>`

Removes any metadata whose name matches the regular expression *pattern*. The pattern will be case insensitive.

Optional appended modifiers include:

`:subimages= indices-or-names`

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)). Only included subimages will have the attribute changed. If subimages are not set, only the first subimage will be changed, or all subimages if the `-a` command line flag was used.

Examples:

```
# Remove one item only
oiiotool in.jpg --eraseattrib "smpte:TimeCode" -o no_timecode.jpg

# Remove all GPS tags
oiiotool in.jpg --eraseattrib "GPS:.*" -o no_gps_metadata.jpg

# Remove all metadata
oiiotool in.exr --eraseattrib:subimages=all ".*" -o no_metadata.exr
```

`--orientation <orient>`

Explicitly sets the image’s “Orientation” metadata to a numeric value (see Section [Display hints](#) for the numeric codes). This only changes the metadata field that specifies how the image should be displayed, it does NOT alter the pixels themselves, and so has no effect for image formats that don’t support some kind of orientation metadata.

Optional appended modifiers include:

`:subimages= indices-or-names`

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)). Only included subimages will have the attribute changed. If subimages are not set, only the first subimage will be changed, or all subimages if the `-a` command line flag was used.

`--orientcw`

`--orientccw`

`--orient180`

Adjusts the image’s “Orientation” metadata by rotating the suggested viewing orientation 90° clockwise, 90° degrees counter-clockwise, or 180°, respectively, compared to its current setting. This only changes the metadata field that specifies how the image should be displayed, it does NOT alter the pixels themselves, and so has no effect for image formats that don’t support some kind of orientation metadata.

See the `--rotate90`, `--rotate180`, `--rotate270`, and `--reorient` commands for true rotation of the pixels (not just the metadata).

`--origin <neworigin>`

Set the pixel data window origin, essentially translating the existing pixel data window to a different position on the image plane. The new data origin is in the form:

```
[+-]x[+-]y
```

Examples:

```
--origin +20+10      x=20, y=10
--origin +0-40       x=0, y=-40
```

--originoffset <offset>

Alter the data window origin, translating the existing pixel data window by this relative amount. The offset is in the form:

```
[+-]x[+-]y
```

Examples:

```
# Assuming the old origin was +100+20...
--originoffset +20+10      # new x=120, y=30
--originoffset +0-40       # new x=100, y=-20
```

--fullsize <size>

Set the display/full window size and/or offset. The size is in the form

width x height [+] xoffset [+] yoffset

If either the offset or resolution is omitted, it will remain unchanged.

Examples:

--fullsize 1920x1080	resolution w=1920, h=1080, offset unchanged
--fullsize -20-30	resolution unchanged, x=-20, y=-30
--fullsize 1024x768+100+0	resolution w=1024, h=768, offset x=100, y=0

--fullpixels

Set the full/display window range to exactly cover the pixel data window.

--chnames <name-list>

Rename some or all of the channels of the top image to the given comma-separated list. Any completely empty channel names in the list will not be changed. For example:

```
oiiotool in.exr --chnames ",,,A,Z" -o out.exr
```

will rename channel 3 to be “A” and channel 4 to be “Z”, but will leave channels 0–3 with their old names.

Optional appended modifiers include:

:subimages=*indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*). Only included subimages will have their channels renamed.

12.8 oiio tool commands that shuffle channels or subimages

--selectmip <level>

If the current image is MIP-mapped, replace the current image with a new image consisting of only the given *level* of the MIPmap. Level 0 is the highest resolution version, level 1 is the next-lower resolution version, etc.

--unmip

If the current image is MIP-mapped, discard all but the top level (i.e., replacing the current image with a new image consisting of only the highest-resolution level). Note that this is equivalent to `--selectmip 0`.

--subimage <n>

If the current image has multiple subimages, replace it with just the specified subimage. The subimage specifier *n* is either an integer giving the index of the subimage to extract (starting with 0), or the *name* of the subimage to extract (comparing to the "oiio:subimagename" metadata).

Additionally, this command can be used to remove one subimage (leaving the others) by using the optional modifier `--subimage:delete=1`.

--sisplit

Remove the top image from the stack, split it into its constituent subimages, and push them all onto the stack (first to last).

--siappend

Replaces the top two (or more) images on the stack with a single new multi-subimage comprised of the original images appended together as subimages within the same single image.

Optional appended modifiers include:

:n= *number-of-subimages*

Specify the number (if more than 2) of images to combine into a single multi-subimage image.

This will be clamped between 2 and the total number of images on the stack.

--siappendall

Replace *all* of the individual images on the stack with a single new image comprised of the subimages of all original images appended together.

--ch <channellist>

Replaces the top image with a new image whose channels have been reordered as given by the *channellist*. The *channellist* is a comma-separated list of channel designations, each of which may be

- an integer channel index of the channel to copy,
- the name of a channel to copy,
- *newname* = *oldname*, which copies a named channel and also renames it,
- = *float*, which will set the channel to a constant value, or
- *newname* = *float*, which sets the channel to a constant value as well as names the new channel.

Example channel lists include: R,G,B,R=0.0,G,B,A=1.0,R=B,G,B=R,4,5,6,A.

Channel numbers outside the valid range of input channels, or unknown names, will be replaced by black channels. If the *channellist* is shorter than the number of channels in the source image, unspecified channels will be omitted.

If the channel list does not specify any changes (neither order, nor name, nor value), then this will just leave the images as-is, without any unnecessary expense or pointless copying of images in memory.

--chappend

Replaces the top two (or more) images on the stack with a single new image comprised of the channels of the input images appended together.

Optional appended modifiers include:

:n= *number-of-subimages*

Specify the number (if more than 2) of images whose channels should be combined into a single image. This will be clamped between 2 and the total number of images on the stack.

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

12.9 oiiotool commands that adjust the image stack

--label <name>

Gives a name to (and saves) the current image at the top of the stack. Thereafter, the label name may be used to refer to that saved image, in the usual manner that an ordinary input image would be specified by filename.

The name of the label must be in the form of an “identifier” (a sequence of alphanumeric characters and underscores, starting with a letter or underscore).

--dup

Duplicate the current image and push the duplicate on the stack. Note that this results in both the current and the next image on the stack being identical copies.

--swap

Swap the current image and the next one on the stack.

--pop

Pop the image stack, discarding the current image and thereby making the next image on the stack into the new current image.

--popbottom

Remove and discard the bottom image from the image stack. (Added in OIIO 3.0.)

--stackreverse

Reverse the order of the entire stack, i.e. making the top be the new bottom and the old bottom be the new top. (Added in OIIO 3.0.)

--stackextract <index>

Move the indexed item (0 for the top of the stack, 1 for the next item down, etc.) to the top of the stack, preserving the relative order of all other items. (Added in OIIO 3.0.)

--stackclear <index>

Remove all items from the stack, leaving it empty and with no “current” image. (Added in OIIO 3.0.)

12.10 oiiotool commands that make entirely new images

--create <size> <channels>

Create new black image with the given size and number of channels, pushing it onto the image stack and making it the new current image.

The *size* is in the form

width x height [+*-*] *xoffset* [+*-*] *yoffset*

If the offset is omitted, it will be *x*=0, *y*=0. Optional appended arguments include:

- **type=** *name* : Create the image in memory with the named data type (default: float).

Examples:

```
--create 1920x1080 3          # RGB with w=1920, h=1080, x=0, y=0
--create 1024x768+100+0 4     # RGBA with w=1024, h=768, x=100, y=0
--create:type=uint8 1920x1080 3 # RGB, store internally as uint8
```

--pattern <patternname> <size> <channels>

Create new image with the given size and number of channels, initialize its pixels to the named pattern, and push it onto the image stack to make it the new current image.

The *size* is in the form

width x height [+*-*] *xoffset* [+*-*] *yoffset*

If the offset is omitted, it will be *x*=0, *y*=0. Optional appended arguments include:

- **type=** *name* : Create the image in memory with the named data type (default: float).

The patterns recognized include the following:

- **black** : A black image (all pixels 0.0)
- **constant** : A constant color image, defaulting to white, but the color can be set with the optional **:color=r,g,b,...** arguments giving a numerical value for each channel.
- **checker** : A black and white checkerboard pattern. The optional modifier **:width=** sets the width of the checkers (defaulting to 8 pixels), **:height=** sets the height of the checkers (defaulting to equal height and width). Optional modifiers **:color1=r,g,b,...** and **:color2=r,g,b,...** set the colors of the alternating squares (defaulting to black and white, respectively).
- **fill** : A constant color or gradient, depending on the optional colors. Argument **:color=r,g,b,...** results in a constant color. Argument **:top=r,g,b,...:bottom=...** results in a top-to-bottom gradient. Argument **:left=r,g,b,...:right=...** results in a left-to-right gradient. Argument **:topleft=r,g,b,...:topright=...:bottomleft=...:bottomright=...** results in a 4-corner bilinear gradient.
- **noise** : Create a noise image, with the option **:type=** specifying the kind of noise: (1) **gaussian** (default) for normal distribution noise with mean and standard deviation given by **:mean=** and **:stddev=**, respectively (defaulting to 0 and 0.1); (2) **white** (or **uniform**) for uniformly-distributed white noise over the range of values given by options **:min=** and **:max=** (defaults: 0 and 0.1); (3) **blue** for uniformly-distributed blue noise over the range of values given by options **:min=** and **:max=** (defaults: 0 and 0.1); (4) **salt** for “salt and pepper” noise where a portion of pixels given by option **portion=** (default: 0.1) is replaced with value given by option **value=** (default: 0). For any of these noise types, the option **seed=** can be used to change the random number seed and **mono=1** can be used to make monochromatic noise (same value in all channels).

Examples:

A constant 4-channel, 640x480 image with all pixels (0.5, 0.5, 0.1, 1):

```
--pattern constant:color=0.3,0.5,0.1,1.0 640x480 4
```

A 256x256 RGB image with a 16-pixel-wide checker pattern:

```
--pattern checker:width=16:height=16 256x256 3
```

Horizontal, vertical, or 4-corner gradients:

```
--pattern fill:top=0.1,0.1,0.1:bottom=0,0,0.5 640x480 3
--pattern fill:left=0.1,0.1,0.1:right=0,0.75,0 640x480 3
--pattern fill:topleft=.1,.1,.1:topright=1,0,0:bottomleft=0,1,
  0:bottomright=0,0,1 640x480 3
```

The first example puts uniform noise independently in 3 channels, while the second generates a single greyscale noise and replicates it in all channels.

```
oiiotool --pattern noise:type=uniform:min=1:max=1 256x256 3 -o colornoise.  
→jpg  
oiiotool --pattern noise:type=uniform:min=0:max=1:mono=1 256x256 3 -o_  
→greynoise.jpg}
```

Generate Gaussian noise with mean 0.5 and standard deviation 0.2 for each channel:

```
oiiotool --pattern noise:type=gaussian:mean=0.5:stddev=0.2 256x256 3 -o_  
→gaussnoise.jpg
```

**--kernel** <name> <size>

Create new 1-channel float image big enough to hold the named kernel and size (size is expressed as *width* x *height*, e.g. 5x5). The *width* and *height* are allowed to be floating-point numbers. The kernel image will have its origin offset so that the kernel center is at (0,0), and will be normalized (the sum of all pixel values will be 1.0).

Kernel names can be: gaussian, sharp-gaussian, box, triangle, blackman-harris, mitchell, b-spline, cubic, keys, simon, rifman, disk. There are also catmull-rom and lanczos3 (and its synonym, nuke-lanczos6), but they are fixed-size kernels that don't scale with the width, and are therefore probably less useful in most cases.

Examples:

```
oiiotool --kernel gaussian 11x11 -o gaussian.exr
```

--capture

Capture a frame from a camera device, pushing it onto the image stack and making it the new current image. Optional appended arguments include:

- camera= *num* : Select which camera number to capture (default: 0).

Examples:

```
--capture           # Capture from the default camera
--capture:camera=1  # Capture from camera #1
```

12.11 oiiotool commands that do image processing

--add**--addc** <value>**--addc** <value0,value1,value2...>

Replace the *two* top images with a new image that is the pixel-by-pixel sum of those images (--add), or add a constant color value to all pixels in the top image (--addc).

For --addc, if a single constant value is given, it will be added to all color channels. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different value to add to each channel in the image.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool imageA.tif imageB.tif --add -o sum.jpg
```

```
oiiotool tahoe.jpg --addc 0.5 -o addc.jpg
```

--sub

--subc <value>

--subc <value0,value1,value2...>

Replace the *two* top images with a new image that is the pixel-by-pixel difference between the first and second images (**--sub**), or subtract a constant color value from all pixels in the top image (**--subc**).

For **--subc**, if a single constant value is given, it will be subtracted from all color channels. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different value to subtract from each channel in the image.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--mul

--mulc <value>

--mulc <value0,value1,value2...>

Replace the *two* top images with a new image that is the pixel-by-pixel multiplicative product of those images (**--mul**), or multiply all pixels in the top image by a constant value (**--mulc**).

For `--mulc`, if a single constant value is given, it will be multiplied to all color channels. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different value to multiply with each channel in the image.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
# Scale image brightness to 20% of its original
oiiotool tahoe.jpg --mulc 0.2 -o mulc.jpg
```

--div

--divc <value>

--divc <value0,value1,value2...>

Replace the *two* top images with a new image that is the pixel-by-pixel, channel-by-channel result of the first image divided by the second image (`--div`), or divide all pixels in the top image by a constant value (`--divc`). Division by zero is defined as resulting in 0.

For `--divc`, if a single constant value is given, all color channels will have their values divided by the same value. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different multiplier for each channel in the image, respectively.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--mad

Replace the *three* top images A, B, and C (C being the top of stack, B below it, and A below B), and compute

$A*B+C$, placing the result on the stack. Note that `A B C --mad` is equivalent to `A B --mul C --add`, though using `--mad` may be somewhat faster and preserve more precision.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--invert

Replace the top image with its color inverse. By default, it only inverts the first three channels in order to preserve alpha, but you can override the channel range of the inversion with optional modifiers `chbegin` and `chend`. Channels outside this range will simply be copied, without inversion.

Optional appended modifiers include:

:chbegin= *int*

Override the beginning of the range of channels to be inverted (defaults to 0.)

:chend= *int*

Override the end of the range of channels to be inverted (defaults to 3). Remember that this is one more than the index of the last channel to be inverted.

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiotool tahoe.jpg --inverse -o inverse.jpg
```

--absdiff

--absdiffc <value>

--absdiffc <value0,value1,value2...>

Replace the *two* top images with a new image that is the absolute value of the difference between the first and second images (`--absdiff`), or replace the top image by the absolute value of the difference between each pixel and a constant color (`--absdiffc`).

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--abs

Replace the current image with a new image that has each pixel consisting of the *absolute value* of the old pixel value.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--powc <value>

--powc <value0,value1,value2...>

Raise all the pixel values in the top image to a constant power value. If a single constant value is given, all color channels will have their values raised to this power. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different exponent for each channel in the image, respectively.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--normalize

Normalize the top image. Assuming the first three channels represent a 3D vector, divide each pixel by its length to make it unit length. This function assumes a 3-channel image that represents a 3-vector, or a 4-channel image that represents a 3-vector plus an alpha value. If an alpha channel is present, its value is merely copied, and is not part of the normalization computation.

Optional appended modifiers include:

:incenter= *float*

The pixel value that corresponds to a 0.0 vector value for the input. (default: 0.0)

:outcenter= *float*

The pixel value that corresponds to a 0.0 vector value for the output. (default: 0.0)

:scale= *float*

The desired length of the output vectors. (default: 1.0)

Example:

```
# Normalize a floating point image containing vector values:
oiiotool xyzvectors.exr --normalize -o normalized.exr

# Normalize an unsigned integer image where [-1,1] vector values
# are encoded on [0,1] for both input and output:
oiiotool xyzvectors.tif --normalize:incenter=0.5:outcenter=0.5:scale=0.5 -o
normalized.tif
```

--noise

Alter the top image to introduce noise, with the option **:type=** specifying the kind of noise: (1) **gaussian** (default) for normal distribution noise with mean and standard deviation given by **:mean=** and **:stddev=**, respectively (defaulting to 0 and 0.1); (2) **white** (or **uniform**) for uniformly-distributed independent noise over the range of values given by options **:min=** and **:max=** (defaults: 0 and 0.1); (3) **blue** is also uniformly distributed between **:min=** and **:max=** (defaults: 0 and 0.1), but rather than independent values, low frequencies are suppressed; (4) **salt** for “salt and pepper” noise where a portion of pixels given by option **portion=** (default: 0.1) is replaced with value given by option **value=** (default: 0).

Optional appended modifiers include:

:seed= *int*

Can be used to change the random number seed.

:mono=1

Make monochromatic noise (same value in all channels).

:nchannels= *int*

Limit which channels are affected by the noise.

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
# Add color gaussian noise to an image
oiiotool tahoe.jpg --noise:type=gaussian:stddev=0.1 -o noisy.jpg

# Simulate bad pixels by turning 1% of pixels black, but only in RGB
# channels (leave A alone)
oiiotool tahoe-rgba.tif --noise:type=salt:value=0:portion=0.01:mono=1:nchannels=3 \
-o dropouts.tif
```

**--chsum**

Replaces the top image by a copy that contains only 1 color channel, whose value at each pixel is the sum of all channels of the original image. Using the optional weight allows you to customize the weight of each channel in the sum.

Optional appended modifiers include:

weight= *r,g,...*

Specify the weight of each channel (default: 1).

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiotool RGB.tif --chsum:weight=.2126,.7152,.0722 -o luma.tif
```

**--contrast**

Remap pixel values from [black, white] to [min, max], with an optional smooth sigmoidal contrast stretch as well.

Optional appended modifiers include:

black= vals

Specify black value(s), default 0.0.

white= vals

Specify white value(s), default 1.0.

min= vals

Specify the minimum range value(s), default 0.0.

max= vals

Specify the maximum range value(s), default 1.0.

scontrast= vals

Specify sigmoidal contrast slope value(s), default 1.0.

sthresh= vals

Specify sigmoidal threshold value(s) giving the position of maximum slope, default 0.5.

clamp= on

If *on* is nonzero, will optionally clamp all result channels to [min,max].

:subimages= indices-or-names

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)).

Each *vals* may be either a single floating point value for all channels, or a comma-separated list of per-channel values.

Examples:

```
oiiotool tahoe.tif --contrast:black=0.1:white=0.75 -o linstretch.tif
oiiotool tahoe.tif --contrast:black=1.0:white=0.0:clamp=0 -o inverse.tif
oiiotool tahoe.tif --contrast:scontrast=5 -o sigmoid.tif
```

**--saturate** <scale>

Scale the saturation of the first three color channels of the image by the scale: 0.0 fully desaturates the image into its greyscale luminance equivalent image, 1.0 leaves the image unchanged, scale values inside this range interpolate between them, and scale > 1 would increase apparent color saturation.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool tahoe.exr --saturate 0 -o grey.exr
oiiotool tahoe.exr --saturate 2 -o colorful.exr
```

This command was added in OIIO 2.4.

--colormap <mapname>

Creates an RGB color map based on the luminance of the input image. The mapname may be one of: “magma”, “inferno”, “plasma”, “viridis”, “turbo”, “blue-red”, “spectrum”, and “heat”. Or, mapname may also be a comma-separated list of RGB triples, to form a custom color map curve.

Note that “magma”, “inferno”, “plasma”, “viridis” are perceptually uniform, strictly increasing in luminance, look good when converted to grayscale, and work for people with all types of colorblindness. The “turbo” color map also shares all of these qualities except for being strictly increasing in luminance. These are all desirable qualities that are lacking in the other, older, crappier maps (blue-red, spectrum, and heat). Don’t be fooled by the flashy “spectrum” colors — it is an empirically bad color map compared to the preferred ones.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiotool tahoe.jpg --colormap inferno -o inferno.jpg
oiiotool tahoe.jpg --colormap viridis -o viridis.jpg
oiiotool tahoe.jpg --colormap turbo -o turbo.jpg
oiiotool tahoe.jpg --colormap .25,.25,.25,0,.5,0,1,0,0 -o custom.jpg
```

--cryptomatte-colors <name>

Creates an RGB image from the input image that contains Cryptomatte channels based on the given name, i.e. <name> followed by a 2-digit number (00, 01, ...) followed by the channels (.red, .green, .blue, .alpha). Each Cryptomatte ID in the input will be given a unique color in the output image.

This command was added in OpenImageIO 2.6.

Example:

```
oiiotool crypto.exr --cryptomatte-colors "CryptoAsset" -o matte.exr
```

--paste <location>

Takes two images – the first is the “foreground” and the second is the “background” – and uses the pixels of the foreground to replace those of the background, with foreground pixel (0,0) being pasted to the background at the *location* specified (expressed as +xpos+ypos, e.g., +100+50, or of course using - for negative offsets). Only pixels within the actual data region of the foreground image are pasted in this manner.

Note that if location is +0+0, the foreground image’s data region will be copied to its same position in the background image (this is useful if you are pasting an image that already knows its correct data window offset).

Optional appended modifiers include:

- **mergeroi=1** : If the value is nonzero, the result image will be sized to be the *union* of the input images (versus being the same data window as the background image). (The **mergeroi** modifier was added in OIIO 2.1.)
- **all=1** : If the value is nonzero, will paste *all* images on the image stack, not just the top two images. This can be useful to paste-merge many images at once, for example, if you have rendered a large image in abutting tiles and wish to re-assemble them into a single image. (The **all** modifier was added in OIIO 2.1.)

Examples:

```
# Result will be the size of bg, but with fg on top and with an
# offset of (100,100).
oiiotool fg.exr bg.exr -paste +100+100 -o out.exr

# Use "merge" mode, so result will be sized to contain both fg
# and bg. Also, paste fg into its natural position given by its
# data window.
oiiotool fg.exr bg.exr -paste:mergeroi=1 +0+0 -o out.exr
```

(continues on next page)

(continued from previous page)

```
# Merge many non-overlapping "tiles" into one combined image
oiiotool img*.exr -paste:mergeroi=1:all=1 +0+0 -o combined.exr
```

--pastemeta <location>

Takes two images – the first will be a source of metadata only, and the second the source of pixels – and produces a new copy of the second image with the metadata from the first image added.

The output image's pixels will come only from the second input. Metadata from the second input will be preserved if no identically-named metadata was present in the first input image.

Examples:

```
# Add all the metadata from meta.exr to pixels.exr and write the
# combined image to out.exr.
oiiotool meta.exr pixels.exr --pastemeta -o out.exr
```

--mosaic <size>

Removes $w \times h$ images from the stack, dictated by the *size*, and turns them into a single image mosaic – an image that comprises $w \times h$ “cells” each containing one of the constituent images.

If there are fewer images on the stack than the number of cells requested, the last cells will be black.

By default, the size of the “cell” is simply the largest of the constituent images, but the optional *fit* parameter can instead dictate the cell size and constituent images will be resized to fit this cell size.

Optional appended modifiers include:

- *fit= WxH* : Sets the dimensions to which the constituent images will be resized as they are assembled into the mosaic.
- *pad= num* : Select the number of pixels of black padding to add between images (default: 0).

Examples:

```
oiiotool left.tif right.tif --mosaic:pad=16 2x1 -o out.tif
oiiotool 0.tif 1.tif 2.tif 3.tif 4.tif --mosaic:pad=16:fit=320x240 2x2 -o out.tif
```

**--over**

Replace the *two* top images with a new image that is the Porter/Duff “over” composite with the first image as the foreground and the second image as the background. Both input images must have the same number and order of channels and must contain an alpha channel.

Optional appended modifiers include:

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--zover

Replace the *two* top images with a new image that is a *depth composite* of the two images – the operation is the Porter/Duff “over” composite, but each pixel individually will choose which of the two images is the foreground and which background, depending on the “Z” channel values for that pixel (larger Z means farther away). Both input images must have the same number and order of channels and must contain both depth/Z and alpha channels. Optional appended modifiers include:

zeroisinf= num

If nonzero, indicates that z=0 pixels should be treated as if they were infinitely far away. (The default is 0, meaning that “zero means zero.”).

:subimages= indices-or-names

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)).

--rotate90

Replace the current image with a new image that is rotated 90 degrees clockwise.

Optional appended modifiers include:

:subimages= indices-or-names

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)).

Example:

```
oiiotool grid.jpg --rotate90 -o rotate90.jpg
```

**--rotate180**

Replace the current image with a new image that is rotated by 180 degrees.

Optional appended modifiers include:

:subimages= indices-or-names

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)).

Example:

```
oiiotool grid.jpg --rotate180 -o rotate180.jpg
```

**--rotate270**

Replace the current image with a new image that is rotated 270 degrees clockwise (or 90 degrees counter-clockwise).

Optional appended modifiers include:

:subimages=*indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiotool grid.jpg --rotate270 -o rotate270.jpg
```

**--flip**

Replace the current image with a new image that is flipped vertically, with the top scanline becoming the bottom, and vice versa.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiotool grid.jpg --flip -o flip.jpg
```

--flop

Replace the current image with a new image that is flopped horizontally, with the leftmost column becoming the rightmost, and vice versa.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiotool grid.jpg --flop -o flop.jpg
```

**--reorient**

Replace the current image with a new image that is rotated and/or flipped as necessary to move the pixels to match the Orientation metadata that describes the desired display orientation.

Example:

```
oiiotool tahoe.jpg --reorient -o oriented.jpg
```

--transpose

Replace the current image with a new image that is reflected about the x-y axis (x and y coordinates and sizes are swapped).

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)).

Example:

```
oiiotool grid.jpg --transpose -o transpose.jpg
```

**--cshift** <offset>

Circularly shift the pixels of the image by the given offset (expressed as +10+100 to move by 10 pixels horizontally and 100 pixels vertically, or +50-30 to move by 50 pixels horizontally and -30 pixels vertically. *Circular* shifting means that the pixels wrap to the other side as they shift.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiotool grid.jpg --cshift +70+30 -o cshift.jpg
```

--crop <size>

Replace the current image with a new copy with the given *size*, cropping old pixels no longer needed, padding black pixels where they previously did not exist in the old image, and adjusting the offsets if requested.

The size is in the form

width x height [+*-*] *xoffset* [+*-*] *yoffset*

or

xmin,ymin,xmax,ymax

Note that **crop** does not *reposition* pixels, it only trims or pads to reset the image's pixel data window to the specified region.

If **oiiotool**'s global **-a** flag is used (**all** subimages), or if the optional **--crop:allsubimages=1** is employed, the crop will be applied identically to all subimages.

Examples:

```
# Both of these crop to a 100x120 region that begins at x=35,y=40
oiiotool tahoe.exr --crop 100x120+35+40 -o crop.exr
oiiotool tahoe.exr --crop 35,40,134,159 -o crop.exr
```

**--croptofull**

Replace the current image with a new image that is cropped or padded as necessary to make the pixel data window exactly cover the full/display window.

--trim

Replace the current image with a new image that is cropped to contain the minimal rectangular ROI that contains all of the nonzero-valued pixels of the original image.

Examples:

```
oiiotool greenrect.exr -trim -o trimmed.jpg

.. image:: figures/pretrim.jpg
   :width: 1.5 in
.. image:: figures/trim.jpg
   :width: 1.5 in
```

--cut <size>

Replace the current image with a new copy with the given *size*, cropping old pixels no longer needed, padding black pixels where they previously did not exist in the old image, repositioning the cut region at the image origin (0,0) and resetting the full/display window to be identical to the new pixel data window. (In other words, --cut is equivalent to --crop followed by --origin +0+0 --fullpixels.)

The size is in the form

width x height [+/-] xoffset [+/-] yoffset

or

xmin,ymin,xmax,ymax

Examples:

```
# Both of these crop to a 100x120 region that begins at x=35,y=40
oiiotool tahoe.exr --cut 100x120+35+40 -o cut.exr
oiiotool tahoe.exr --cut 35,40,134,159 -o cut.exr
```

--resample <size>

Replace the current image with a new image that is resampled to the given pixel data resolution rapidly, but at a low quality, either by simple bilinear interpolation or by just copying the “closest” pixel. The size is in the form of any of these:

width x height

width x height [+/-] xoffset [+/-] yoffset

xmin,ymin,xmax,ymax

wscale% x hscale%

if *width* or *height* is 0, that dimension will be automatically computed so as to preserve the original aspect ratio.

Optional appended modifiers include:

interp= bool

If set to zero, it will just copy the “closest” pixel; if nonzero, bilinear interpolation of the surrounding 4 pixels will be used.

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples (suppose that the original image is 640x480):

```
--resample 1024x768      # new resolution w=1024, h=768
--resample 50%           # reduce resolution to 320x240
--resample 300%          # increase resolution to 1920x1440
--resample 400x0         # new resolution will be 400x300
```

--resize <size>

Replace the current image with a new image whose display (full) size is the given pixel data resolution and offset. The *size* is in the form

width x height

width x height [+/-] xoffset [+/-] yoffset

xmin,ymin,xmax,ymax

scale%

wscale% x hscale%

If *width* or *height* is 0, that dimension will be automatically computed so as to preserve the original aspect ratio.

By default, the scaling that occurs is to map the *full/display* window area of the input image to the full/display window of the output image (determined by the *size* argument). However, a more general warping can be specified using any of the *:from=*, *:to=*, or *:offset=* optional modifiers. (These modifiers were added in OpenImageIO 2.5.)

Optional appended modifiers include:

:from= size

The region (specified in any of the same forms as the *size* argument, with decimal / partial pixel sizes and offsets allowed) of the source image that defines the transformational mapping. This defaults to the full/display window of the source image.

:to= *size*

The region (specified in any of the same forms as the *size* argument, with decimal / partial pixel sizes and offsets allowed) of the destination image that defines the transformational mapping. This defaults to the full/display window of the destination image.

:filter= *name*

Filter name. The default is `blackman-harris` when increasing resolution, `lanczos3` when decreasing resolution.

:highlightcomp= *val*

If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of `--rangecompress` and `--rangeexpand`, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.

:edgeclamp= *bool*

If nonzero, clamp the image to the edge pixels before filtering. This might help with certain edge ringing situations. The default is 0 (off).

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples (suppose that the original image is 640x480):

```
--resize 1024x768      # new resolution w=1024, h=768
--resize 50%           # reduce resolution to 320x240
--resize 300%          # increase resolution to 1920x1440
--resize 400x0         # new resolution will be 400x300

# Create a 1024x768 image that is a resized and shifted version
# of the original, where the upper left 100x100 section of the
# original maps to a 200x200 region starting at the 50,50
# coordinates of the new image.
--resize:from=100x100:to=200x200+50+50 1024x768

# Resize to 320x240, but with an additional 1/2 pixel shift in
# each direction.
--resize:offset=+0.5+0.5 320x240
```

--fit <size>

Replace the current image with a new image that is resized to fit into the given pixel data resolution, keeping the original aspect ratio and padding with black pixels if the requested image size does not have the same aspect ratio. The *size* is in the form

width x height

width x height [+/-] *xoffset* [+/-] *yoffset*

Optional appended modifiers include:

- **filter= *name*** : Filter name. The default is `blackman-harris` when increasing resolution, `lanczos3` when decreasing resolution.
- **highlightcomp= *val*** : If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of `--rangecompress` and `--rangeexpand`, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.
- **fillmode= *mode*** : determines which of several methods will be used to determine how the image will fill the new frame, if its aspect ratio does not precisely match the original source aspect ratio:

- “width” exactly fills the width of the new frame, either cropping or letterboxing the height if it isn’t precisely the right size to preserve the original aspect ratio.
- “height” exactly fills the height of the new frame, either cropping or letterboxing the width if it isn’t precisely the right size to preserve the original aspect ratio.
- “letterbox” (the default) chooses whichever of “width” or “height” will maximally fill the new frame with no image data lost (it will only letterbox, never crop).
- `pad= p` : If the argument is nonzero, will pad with black pixels to make the resulting image exactly the size specified, if the source and desired size are not the same aspect ratio.
- `exact= e` : If the argument is nonzero, will result in an exact match on aspect ratio and centering (partial pixel shift if necessary), whereas the default (0) will only preserve aspect ratio and centering to the precision of a whole pixel.
- `wrap= wrapmode` : For “exact” aspect ratio fitting, this determines the wrap mode used for the resizing kernel (default: `black`, other choices include `clamp`, `periodic`, `mirror`).

Examples:

```
oiiotool in.exr --fit:pad=1:exact=1 640x480 -o out.exr
```

```
oiiotool in.exr --fit 1024x1024 -o out.exr
```

Examples of an image being fit into a frame that is wider than the original aspect ratio with fill mode: (a) original, (b) “width”, (c) “height”, (d) “letterbox”.

Examples of an image being fit into a frame that is narrower than the original aspect ratio with fill mode: (a) original, (b) “width”, (c) “height”, (d) “letterbox”.

--pixelaspect <aspect>

Replace the current image with a new image that scales up the width or height in order to match the requested pixel aspect ratio. If displayed in a manner that honors the PixelAspectRatio, it should look the same, but it will have different pixel dimensions than the original. It will always be the same or higher resolution, so it does not lose any detail present in the original.

As an example, if you have a 512x512 image with pixel aspect ratio 1.0, `--pixelaspect 2.0` will result in a 512x1024 image that has “PixelAspectRatio” metadata set to 2.0.

Optional appended modifiers include:

- `:filter= name` : Filter name. The default is `lanczos3`.
- `:highlightcomp= val` : If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of `--rangecompress` and `--rangeexpand`, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.

Examples:

```
oiiotool mandrill.tif --pixelaspect 2.0 -o widepixels.tif
```

--rotate <angle>

Replace the current image with a new image that is rotated by the given angle (in degrees). Positive angles mean to rotate counter-clockwise, negative angles mean clockwise. By default, the center of rotation is at the exact center of the display window (a.k.a. “full” image), but can be explicitly set with the optional `center=x,y` option.

Optional appended modifiers include:

:center= x,y

Alternate center of rotation.

:filter= name

Filter name. The default is lanczos3.

:highlightcomp= val

If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of `--rangecompress` and `--rangeexpand`, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.

:recompute_roi= val

If nonzero, recompute the pixel data window to exactly hold the transformed image (default=0).

:subimages= indices-or-names

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)).

Examples:

```
oiiotool mandrill.tif --rotate 45 -o rotated.tif
```

```
oiiotool mandrill.tif --rotate:center=80,91.5:filter=lanczos3 45 -o rotated.tif
```

--warp <M33>

Replace the current image with a new image that is warped by the given 3x3 matrix (presented as a comma-separated list of values, without any spaces).

Optional appended modifiers include:

:filter= *name*

Filter name. The default is `lanczos3`.

:highlightcomp= *val*

If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of `--rangecompress` and `--rangeexpand`, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.

:recompute_roi= *val*

If nonzero, recompute the pixel data window to exactly hold the transformed image (default=0).

:wrap= *wrapmode*

The wrap mode to use when sampling the image for the warp. The default is `black`; other choices include `clamp`, `periodic`, `mirror`.

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool mandrill.tif --warp "0.707,0.707,0,-0.707,0.707,0,128,-53.02,1" -o warped.  
↳tif
```

--st_warp

Use the top image as a set of normalized `st` image coordinates to warp the second image in the stack.

Optional appended modifiers include:

filter= *name*

Filter name. The default is `lanczos3`.

chan_s= *index*

The index of the `s` channel in the `st` image (default=0).

chan_t= *index*

The index of the `t` channel in the `st` image (default=1).

flip_s= *bool*

If nonzero, mirror the `s` coordinates along the horizontal axis. Useful for coordinates authored in terms of an origin other than the upper-left corner (default=0).

flip_t= *bool*

If nonzero, mirror the `t` coordinates along the vertical axis. Useful for coordinates authored in terms of an origin other than the upper-left corner (default=0).

Examples:

```
oiiotool mandrill.tif distortion_st.tif --st_warp -o mandrill_distorted.tif  
  
# Using an `st` map authored in terms of a lower-left origin (e.g. by  
# Nuke), so flip the vertical (`t`) coordinate.  
oiiotool mandrill.tif st_from_nuke.tif --st_warp:filter=triangle:flip_t=1 -o  
↳mandrill_distorted.tif
```

--convolve

Use the top image as a kernel to convolve the next image farther down the stack, replacing both with the result.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
# Use a kernel image already prepared
oiiotool image.exr kernel.exr --convolve -o output.exr

# Construct a kernel image on the fly with --kernel
oiiotool image.exr --kernel gaussian 5x5 --convolve -o blurred.exr
```

--blur <size>

Blur the top image with a blur kernel of the given size expressed as *width x height*. (The sizes may be floating point numbers.)

Optional appended modifiers include:

kernel= *name*

Kernel name. The default is gaussian.

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool image.jpg --blur 5x5 -o blurred.jpg

oiiotool image.jpg --blur:kernel=bspline 7x7 -o blurred.jpg
```

**--median <size>**

Perform a median filter on the top image with a window of the given size expressed as *width x height*. (The sizes are integers.) This helps to eliminate noise and other unwanted high-frequency detail, but without blurring long edges the way a `--blur` command would.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool noisy.jpg --median 3x3 -o smoothed.jpg
```

--dilate <size>

--erode <size>

Perform dilation or erosion on the top image with a window of the given size expressed as *width x height*. (The sizes are integers.) Dilation takes the maximum of pixel values inside the window, and makes bright features wider and more prominent, dark features thinner, and removes small isolated dark spots. Erosion takes the minimum of pixel values inside the window, and makes dark features wider, bright features thinner, and removes small isolated bright spots.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)).

Examples:

```
oiiotool orig.tif --dilate 3x3 -o dilate.tif
oiiotool orig.tif --erode 3x3 -o erode.tif
oiiotool orig.tif --erode 3x3 --dilate 3x3 -o open.tif
oiiotool orig.tif --dilate 3x3 --erode 3x3 -o close.tif
oiiotool orig.tif --dilate 3x3 --erode 3x3 -sub -o gradient.tif
oiiotool orig.tif open.tif -o tophat.tif
oiiotool close.tif orig.tif -o bottomhat.tif
```

--laplacian

Calculates the Laplacian of the top image.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool tahoe.jpg --laplacian tahoe-laplacian.exr
```

--unsharp

Unblur the top image using an “unsharp mask.”

Optional appended modifiers include:

kernel= *name*

Name of the blur kernel (default: `gaussian`). If the kernel name is `median`, the unsharp mask algorithm will use a median filter rather than a blurring filter in order to compute the low-frequency image.

width= *w*

Width of the blur kernel (default: 3).

contrast= *c*

Contrast scale (default: 1.0)

threshold= *t*

Threshold for applying the difference (default: 0)

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool image.jpg --unsharp -o sharper.jpg

oiiotool image.jpg --unsharp:width=5:contrast=1.5 -o sharper.jpg

oiiotool image.jpg --unsharp:kernel=median -o sharper.jpg
# Note: median filter helps emphasize compact high-frequency details
# without over-sharpening long edges as the default unsharp filter
# sometimes does.
```

--fft

--ifft

Performs forward and inverse unitized discrete Fourier transform. The forward FFT always transforms only the first channel of the top image on the stack, and results in a 2-channel image (with real and imaginary channels). The inverse FFT transforms the first two channels of the top image on the stack (assuming they are real and imaginary, respectively) and results in a single channel result (with the real component only of the spatial domain result).

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
# Select the blue channel and take its DCT
oiiotool image.jpg --ch 2 --fft -o fft.exr

# Reconstruct from the FFT
oiiotool fft.exr --ifft -o reconstructed.exr

# Output the power spectrum: real^2 + imag^2
oiiotool fft.exr --dup --mul --chsum -o powerspectrum.exr
```

--polar**--unpolar**

The **--polar** transforms a 2-channel image whose channels are interpreted as complex values (real and imaginary components) into the equivalent values expressed in polar form of amplitude and phase (with phase between 0 and 2π).

The **unpolar** performs the reverse transformation, converting from polar values (amplitude and phase) to complex (real and imaginary).

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool complex.exr --polar -o polar.exr
oiiotool polar.exr --unpolar -o complex.exr
```

--fixnan <strategy>

Replace the top image with a copy in which any pixels that contained NaN or Inf values (hereafter referred to collectively as “nonfinite”) are repaired. If *strategy* is **black**, nonfinite values will be replaced with 0. If *strategy* is **box3**, nonfinite values will be replaced by the average of all the finite values within a 3x3 region surrounding the pixel. If *strategy* is **error**, nonfinite values will be left alone, but it will result in an error that will terminate **oiiotool**.

--max**--maxc** <value>**--maxc** <value0,value1,value2...>**--min****--minc** <value>

--minc <value0,value1,value2...>

Replace the *two* top images with a new image that is the pixel-by-pixel maximum of those images (**--max**) or minimum (**--min**) of the corresponding pixels of each image, or the min/max of each pixel of one image with a constant color (**--maxc**, **--minc**).

For **--maxc** and **--minc**, if a single constant value is given, it will be used for all color channels. Alternatively, a series of comma-separated constant values (with no spaces) may be used to specify a different value to add to each channel in the image.

Optional appended modifiers include:

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool imageA.tif imageB.tif --min -o minimum.tif
```

```
# Clamp all channels to a minimum of 0 (all negative values are # changed to 0). oiiotool input.exr
--minc 0.0 -o nonegatives.exr
```

--clamp

Replace the top image with a copy in which pixel values have been clamped. Optional arguments include:

Optional appended modifiers include:

- **min= val** : Specify a minimum value for all channels.
- **min= val0,val1,...** : Specify minimum value for each channel individually.
- **max= val** : Specify a maximum value for all channels.
- **max= val0,val1,...** : Specify maximum value for each channel individually.
- **clampalpha= val** : If *val* is nonzero, will additionally clamp the alpha channel to [0,1]. (Default: 0, no additional alpha clamp.)

If no value is given for either the minimum or maximum, it will NOT clamp in that direction. For the variety of minimum and maximum that specify per-channel values, a missing value indicates that the corresponding channel should not be clamped.

Examples:

- **--clamp:min=0** : Clamp all channels to a minimum of 0 (all negative values are changed to 0).
- **--clamp:min=0:max=1** : Clamp all channels to [0,1].
- **--clamp:clampalpha=1** : Clamp the designated alpha channel to [0,1].
- **--clamp:min=,,0:max=,,3.0** : Clamp the third channel to [0,3], do not clamp & other channels.

--maxchan**--minchan**

Replace the top image with a single channel image that, for each pixel, contains the maximum value (for **--maxchan**) or minimum value (for **--minchan**) of all the channels in the corresponding pixel of the original image.

This command was first added to OpenImageIO 2.4.0.

Optional appended modifiers include:

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool RGB.tif --maxchan -o max_of_RGB.tif
```

--rangecompress**--rangeexpand**

Range compression re-maps input values to a logarithmic scale. Range expansion is the inverse mapping back to a linear scale. Range compression and expansion only applies to color channels; alpha or z channels will not be modified.

By default, this transformation will happen to each color channel independently. But if the optional `luma` argument is nonzero and the image has at least 3 channels and the first three channels are not alpha or depth, they will be assumed to be RGB and the pixel scaling will be done using the luminance and applied equally to all color channels. This can help to preserve color even when remapping intensity.

Optional appended modifiers include:

luma= *val*

val is 0, turns off the luma behavior.

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Range compression and expansion can be useful in cases where high contrast super-white (> 1) pixels (such as very bright highlights in HDR captured or rendered images) can produce undesirable artifacts, such as if you resize an HDR image using a filter with negative lobes – which could result in objectionable ringing or even negative result pixel values. For example:

```
oiiotool hdr.exr --rangecompress --resize 512x512 --rangeexpand -o resized.exr
```

--fillholes

Replace the top image with a copy in which any pixels that had $\alpha < 1$ are “filled” in a smooth way using data from surrounding $\alpha > 0$ pixels, resulting in an image that is $\alpha = 1$ and plausible color everywhere. This can be used both to fill internal “holes” as well as to extend an image out.

--box <x1,y1,x2,y2>

Draw (rasterize) a filled or unfilled a box with opposite corners (x1,y1) and (x2,y2). Additional optional arguments include:

color= *r,g,b,...*

specify the color of the lines

fill= *bool*

if nonzero, fill in the box

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

The default color, if not supplied, is opaque white.

Examples:

```
oiiotool checker.exr --box:color=0,1,1,1 150,100,240,180 \  
--box:color=0.5,0.5,0,0.5:fill=1 100,50,180,140 -o out.exr
```

--line <x1,y1,x2,y2,...>

Draw (rasterize) an open polyline connecting the list of pixel positions, as a comma-separated list of alternating x and y values. Additional optional arguments include:

color= *r,g,b,...*

specify the color of the line

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

The default color, if not supplied, is opaque white.

Examples:

```
oiiotool checker.exr --line:color=1,0,0 10,60,250,20,100,190 -o out.exr
```

--point <x1,y1,x2,y2,...>

Draw single points at the list of pixel positions, as a comma-separated list of alternating x and y values. Additional optional arguments include:

color= *r,g,b,...*

specify the color of the line

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

The default color, if not supplied, is opaque white.

Examples:

```
oiiotool checker.exr --point:color=1,0,0 10,60,250,20,100,190 -o out.exr
```

--fill <size>

Alter the top image by filling the ROI specified by *size*. The fill can be a constant color, vertical gradient, horizontal gradient, or four-corner gradient.

Optional modifiers for constant color:

color= *r,g,b,...*
the color of the constant

Optional modifiers for vertical gradient:

top= *r,g,b,...*
the color for the top edge of the region

bottom= *r,g,b,...*
the color for the bottom edge of the region

Optional modifiers for horizontal gradient:

left= *r,g,b,...*
the color for the left edge of the region

right= *r,g,b,...*
the color for the right edge of the region

Optional modifiers for 4-corner gradient:

topleft= *r,g,b,...*
the color for the top left corner of the region

topright= *r,g,b,...*
the color for the top right corner of the region

bottomleft= *r,g,b,...*
the color for the bottom left corner of the region

bottomright= *r,g,b,...*
the color for the bottom right corner of the region

Examples:

```
# make a grey-to-blue vertical gradient
oiiotool --create 640x480 3 \
  --fill:top=0.1,0.1,0.1:bottom=0,0,0.5 640x480 -o gradient.tif

# make a grey-to-green horizontal gradient
oiiotool --create 640x480 3 \
  --fill:left=0.1,0.1,0.1:right=0,0.75,0 640x480 -o gradient.tif

# four-corner interpolated gradient
```

(continues on next page)

(continued from previous page)

```
oiiotool --create 640x480 3 \
  -fill:topleft=.1,.1,.1:topright=1,0,0:bottomleft=0,1,0:bottomright=0,0,1 \
  640x480 -o gradient.tif
```

--text <words>

Draw (rasterize) text overtop of the current image.

Optional appended modifiers include:

x= *xpos*

x position (in pixel coordinates) of the text

y= *ypos*

y position (in pixel coordinates) of the text

size= *size*

font size (height, in pixels)

font= *name*

font name, full path to the font file on disk (use double quotes "*name*" if the path name includes spaces or a colon)

color= *r,g,b,...*

specify the color of the text

xalign= *val*

controls horizontal text alignment: left (default), right, center.

yalign= *val*

controls vertical text alignment: base (default), top, bottom, center.

shadow= *size*

if nonzero, will make a dark shadow halo to make the text more clear on bright backgrounds.

:subimages= *indices-or-names*

Include/exclude subimages (see [Dealing with multi-subimage/multi-part files](#)).

The default positions the text starting at the center of the image, drawn 16 pixels high in opaque white in all channels (1,1,1,...), and using a default font (which may be system dependent).

Examples:

```
oiiotool --create 320x240 3 --text:x=10:y=400:size=40 "Hello world" \
  --text:x=100:y=200:font="Arial Bold":color=1,0,0:size=60 "Go Big Red!" \
  --tocolorspace sRGB -o text.jpg

oiiotool --create 320x240 3 --text:x=160:y=120:xalign=center "Centered" \
  --tocolorspace sRGB -o textcentered.jpg

oiiotool tahoe-small.jpg \
  --text:x=160:y=40:xalign=center:size=40:shadow=0 "shadow = 0" \
  --text:x=160:y=80:xalign=center:size=40:shadow=1 "shadow = 1" \
  --text:x=160:y=120:xalign=center:size=40:shadow=2 "shadow = 2" \
  --tocolorspace sRGB -o textshadowed.jpg
```

Note that because of slightly differing fonts and versions of Freetype available, we do not expect drawn text to be pixel-for-pixel identical on different platforms supported by OpenImageIO.

12.12 oiiotool commands for color management

Many of the color management commands depend on an installation of OpenColorIO (<http://opencolorio.org>).

If OIIO has been compiled with OpenColorIO support and the environment variable `$OCIO` is set to point to a valid OpenColorIO configuration file, you will have access to all the color spaces that are known by that OCIO configuration. Alternately, you can use the `--colorconfig` option to explicitly point to a configuration file. If no valid configuration file is found (either in `$OCIO` or specified by `--colorconfig`) or OIIO was not compiled with OCIO support, then the only color space transformats available are `linear to Rec709` (and vice versa) and `linear to sRGB` (and vice versa).

If you ask for **oiiotool** help (`oiiotool --help`), at the very bottom you will see the list of all color spaces, looks, and displays that **oiiotool** knows about. That information (including even more detail) will be printed with the command `oiiotool --colorconfiginfo`.

--colorconfiginfo

Print to the console extensive information about the color management configuration, including the list of all known color spaces (and their aliases), looks, displays (and their views), as well as which version of OpenColorIO is being used, and the path to the configuration file.

This command was added in OIIO 2.4.6.

--colorconfig <filename>

Instruct **oiiotool** to read an OCIO configuration from a custom location. Without this, the default is to use the `$OCIO` environment variable as a guide for the location of the configuration file.

--iscolorspace <colorspace>

Alter the metadata of the current image so that it thinks its pixels are in the named color space. This does not alter the pixels of the image, it only changes **oiiotool**'s understanding of what color space those those pixels are in.

--colorconvert <fromspace> <tospace>

Replace the current image with a new image whose pixels are transformed from the named *fromspace* color space into the named *tospace* (disregarding any notion it may have previously had about the color space of the current image). Optional appended modifiers include:

- **key= name, value= str :**

Adds a key/value pair to the “context” that OpenColorIO will used when applying the look. Multiple key/value pairs may be specified by making each one a comma-separated list.

- **unpremult= val :**

If the numeric *val* is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

- **strict= val :**

When nonzero (the default), an inability to perform the color transform will be a hard error. If strict is 0, inability to find the transformation will just print a warning and simply copy the image without changing colors.

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--tocolorspace <tospace>

Replace the current image with a new image whose pixels are transformed from their existing color space (as best understood or guessed by OIIO) into the named *tospace*. This is equivalent to a use of `oiiotool --colorconvert` where the *fromspace* is automatically deduced.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--ccmatrix <m00,m01,...>

NEW 2.1

Replace the current image with a new image whose colors are transformed according to the 3x3 or 4x4 matrix formed from the 9 or 16 comma-separated floating-point values in the subsequent argument (spaces are allowed only if the whole collection of values is enclosed in quotes so that they are a single command-line argument).

The values fill in the matrix left to right, first row, then second row, etc. This means that colors are treated as “row vectors” that are post-multiplied by the matrix ($C \cdot M$).

Optional appended modifiers include:

- **unpremult= *val*** :

If the numeric *val* is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

- **invert= *val*** :

If nonzero, this will cause the matrix to be inverted before being applied.

- **transpose= *val*** :

If nonzero, this will cause the matrix to be transposed (this allowing you to more easily specify it as if the color values were column vectors and the transformation as $M \cdot C$).

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
# Convert ACES to ACEScg using a matrix
oiiotool acexr --ccmatrix:transpose=1 \
    "1.454,-0.237,-0.215,-0.077,1.176,-0.010,0.008,-0.006, 0.998" \
    -o acescg.exr
```

--ociolook <lookname>

Replace the current image with a new image whose pixels are transformed using the named OpenColorIO look description. Optional appended arguments include:

- **from= *val***

Assume the image is in the named color space. If no **from=** is supplied, it will try to deduce it from the image’s metadata or previous **--iscolorspace** directives. If no such hints are available, it will assume the pixel data are in the default linear scene-referred color space.

- **to= *val***

Convert to the named space after applying the look.

- **inverse= *val***

If *val* is nonzero, inverts the color transformation and look application.

- **key= *name*, value= *str***

Adds a key/value pair to the “context” that OpenColorIO will used when applying the look. Multiple key/value pairs may be specified by making each one a comma-separated list.

- **unpremult= val :**

If the numeric *val* is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

This command is only meaningful if OIIO was compiled with OCIO support and the environment variable \$OCIO is set to point to a valid OpenColorIO configuration file. If you ask for **oiitool** help (**oiitool --help**), at the very bottom you will see the list of all looks that **oiitool** knows about.

Examples:

```
oiitool in.jpg --ociolook:from=vd8:to=vd8:key=SHOT:value=pe0012 match -o cc.jpg
```

--ociodisplay <displayname> <viewname>

Replace the current image with a new image whose pixels are transformed using the named OpenColorIO “display” transformation given by the *displayname* and *viewname*. The word “default” (or the empty string “”) for *displayname* means to use the default display, and “default” or “” for *viewname* means to use the default view on that display.

Optional appended modifiers include:

from= name

Assume the image is in the named color space. If no **from=** is supplied, it will try to deduce it from the image’s metadata or previous **--iscolorspace** directives. If no such hints are available, it will assume the pixel data are in the default linear scene-referred color space.

key= name, value= str

Adds a key/value pair to the “context” that OpenColorIO will used when applying the look. Multiple key/value pairs may be specified by making each one a comma-separated list.

unpremult= val :

If the numeric *val* is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

inverse= val :

If *val* is nonzero, inverts the color transformation.

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

This command is only meaningful if OIIO was compiled with OCIO support and the environment variable \$OCIO is set to point to a valid OpenColorIO configuration file. If you ask for **oiitool** help (**oiitool --help**), at the very bottom you will see the list of all looks that **oiitool** knows about.

Examples:

```
oiitool in.exr --ociodisplay:from=lnf:key=SHOT:value=pe0012 sRGB Film -o cc.jpg
```

--ociofiletransform <name>

Replace the current image with a new image whose pixels are transformed using the named OpenColorIO file transform. Optional appended arguments include:

- **inverse= val :**

If *val* is nonzero, inverts the color transformation.

- **unpremult= val :**

If the numeric *val* is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool in.jpg --ociofiletransform footransform.csp -o out.jpg
```

--ocionamedtransform <name>

Replace the current image with a new image whose pixels are transformed using the named OpenColorIO named transform. Optional appended arguments include:

- **key= name, value= str**

Adds a key/value pair to the “context” that OpenColorIO will used when applying the look. Multiple key/value pairs may be specified by making each one a comma-separated list.

- **inverse= val :**

If *val* is nonzero, inverts the color transformation.

- **unpremult= val :**

If the numeric *val* is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool in.exr --ocionamedtransform:inverse=1 srgb_crv -o out.jpg
```

--unpremult

Divide all color channels (those not alpha or z) of the current image by the alpha value, to “un-premultiply” them. This presumes that the image starts of as “associated alpha,” a.k.a. “premultiplied.” Pixels in which the alpha channel is 0 will not be modified (since the operation is undefined in that case). This is a no-op if there is no identified alpha channel.

Optional appended modifiers include:

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--premult

Multiply all color channels (those not alpha or z) of the current image by the alpha value, to “premultiply” them. This presumes that the image starts of as “unassociated alpha,” a.k.a. “non-premultiplied.”

Optional appended modifiers include:

:subimages= indices-or-names

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--iccread <filename>

The `--iccread` command adds an "ICCProfile" attribute to the top image, as a byte array consisting of the entire contents of the named file.

This was added to OpenImageIO 2.5.

--iccwrite <filename>

Extract the "ICCProfile" attribute from the top image and writing it to the named file.

This was added to OpenImageIO 2.5.

12.13 oiiotool commands for deep images

A number of **oiiotool** operations are designed to work with “deep” images. These are detailed below. In general, operations not listed in this section should not be expected to work with deep images.

12.13.1 Commands specific to deep images

--deepen

If the top image is not deep, then turn it into the equivalent “deep” image. Pixels with non-infinite \$z\$ or with any non-zero color channels will get a single depth sample in the resulting deep image. Pixels in the source that have 0 in all channels, and either no “Z” channel or a \$z\$ value indicating an infinite distance, will result in a pixel with no depth samples.

Optional appended modifiers include:

z= *val*

The depth to use for deep samples if the source image did not have a “Z” channel. (The default is 1.0.)

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--flatten

If the top image is “deep,” then “flatten” it by compositing the depth samples in each pixel.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--deepmerge

Replace the *two* top images with a new deep image that is the “deep merge” of the inputs. Both input images must be deep images, have the same number and order of channels and must contain an alpha channel and depth channel.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

--deepholdout

Replace the *two* top images with a new deep image that is the “deep holdout” of the first image by the second — that is, the samples from the first image that are closer than the opaque frontier of the second image. Both input inputs must be deep images.

Optional appended modifiers include:

:subimages= *indices-or-names*

Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

12.13.2 General commands that also work for deep images

--addc, --subc, --mulc, --divc

Adding, subtracting, multiplying, or dividing a per-channel constant will work for deep images, performing the operation for every sample in the image.

--autotrim

For subsequent outputs, automatically **--trim** before writing the file.

--ch <channellist>

Reorder, rename, remove, or add channels to a deep image. See Section *oiitool commands that shuffle channels or subimages*

--crop <size>

Crop (adjust the pixel data window), removing pixels or adding empty pixels as needed.

--paste <position>

Replace one image’s pixels with another’s (at an arbitrary offset).

(This functionality was extended to deep images in OIIO 2.1.)

--resample <size>

Resampling (resize without filtering or interpolation, just choosing the closest deep pixel to copy for each output pixel).

Optional appended modifiers include:

- **interp= *val*** : If 0, the “closest” single pixel will be copied for each sample. If 1, the nearest 4 pixels will be interpolated to produce each sample. (Default: 1)

--diff

Report on the difference of the top two images.

--dumpdata

Print to the console detailed information about the values in every pixel.

Optional appended modifiers include:

- **empty= *val*** : If 0, will cause deep images to skip printing of information about pixels with no samples, and cause non-deep images to skip printing information about pixels that are entirely 0.0 value in all channels.

--info

Prints information about each input image as it is read.

--trim

Replace the current image with a new image that is cropped to contain the minimal rectangular ROI that contains all of the non-empty pixels of the original image.

--scanline

--tile <x> <y>

Convert to scanline or to tiled representations upon output.

--stats

Prints detailed statistical information about each input image as it is read.

--fixnan <strategy>

Replace the top image with a copy in which any pixels that contained NaN or Inf values (hereafter referred to collectively as “nonfinite”) are repaired. The *strategy* may be either **black** or **error**.

GETTING IMAGE INFORMATION WITH IINFO

The **iinfo** program will print either basic information (name, resolution, format) or detailed information (including all metadata) found in images. Because **iinfo** is built on top of OpenImageIO, it will print information about images of any formats readable by ImageInput plugins on hand.

13.1 Using iinfo

The **iinfo** utility is invoked as follows:

```
iinfo options filename
```

Where *filename* (and any following strings) names the image file(s) whose information should be printed. The image files may be of any format recognized by OpenImageIO (i.e., for which ImageInput plugins are available).

In its most basic usage, it simply prints the resolution, number of channels, pixel data type, and file format type of each of the files listed:

```
$ iinfo img_6019m.jpg grid.tif lenna.png

img_6019m.jpg : 1024 x 683, 3 channel, uint8 jpeg
grid.tif      : 512 x 512, 3 channel, uint8 tiff
lenna.png     : 120 x 120, 4 channel, uint8 png
```

The **-s** flag also prints the uncompressed sizes of each image file, plus a sum for all of the images:

```
$ iinfo -s img_6019m.jpg grid.tif lenna.png

img_6019m.jpg : 1024 x 683, 3 channel, uint8 jpeg (2.00 MB)
grid.tif      : 512 x 512, 3 channel, uint8 tiff (0.75 MB)
lenna.png     : 120 x 120, 4 channel, uint8 png (0.05 MB)
Total size: 2.81 MB
```

The **-v** option turns on `emph{verbose mode}`, which exhaustively prints all metadata about each image:

```
img_6019m.jpg : 1024 x 683, 3 channel, uint8 jpeg
  channel list: R, G, B
  Color space: sRGB
  ImageDescription: "Family photo"
  Make: "Canon"
  Model: "Canon EOS DIGITAL REBEL XT"
  Orientation: 1 (normal)
  XResolution: 72
```

(continues on next page)

(continued from previous page)

```

YResolution: 72
DateTime: "2008:05:04 19:51:19"
Exif:YCbCrPositioning: 2
ExposureTime: 0.004
FNumber: 11
Exif:ExposureProgram: 2 (normal program)
Exif:ISOSpeedRatings: 400
Exif:DateTimeOriginal: "2008:05:04 19:51:19"
Exif:DateTimeDigitized: "2008:05:04 19:51:19"
Exif:ShutterSpeedValue: 7.96579 (1/250 s)
Exif:ApertureValue: 6.91887 (f/11)
Exif:ExposureBiasValue: 0
Exif:MeteringMode: 5 (pattern)
Exif:Flash: 16 (no flash, flash suppression)
Exif:FocalLength: 27 (27 mm)
Exif:ColorSpace: 1
Exif:PixelXDimension: 2496
Exif:PixelYDimension: 1664
Exif:FocalPlaneXResolution: 2855.84
Exif:FocalPlaneYResolution: 2859.11
Exif:FocalPlaneResolutionUnit: 2 (inches)
Exif:CustomRendered: 0 (no)
Exif:ExposureMode: 0 (auto)
Exif:WhiteBalance: 0 (auto)
Exif:SceneCaptureType: 0 (standard)
Keywords: "Carly; Jack"

```

If the input file has multiple subimages, extra information summarizing the subimages will be printed:

```

$ iinfo img_6019m.tx

img_6019m.tx : 1024 x 1024, 3 channel, uint8 tiff (11 subimages)

$ iinfo -v img_6019m.tx

img_6019m.tx : 1024 x 1024, 3 channel, uint8 tiff
  11 subimages: 1024x1024 512x512 256x256 128x128 64x64 32x32 16x16 8x8 4x4 2x2 1x1
  channel list: R, G, B
  tile size: 64 x 64
  ...

```

Furthermore, the -a option will print information about all individual subimages:

```

$ iinfo -a ../sample-images/img_6019m.tx

img_6019m.tx : 1024 x 1024, 3 channel, uint8 tiff (11 subimages)
  subimage 0: 1024 x 1024, 3 channel, uint8 tiff
  subimage 1: 512 x 512, 3 channel, uint8 tiff
  subimage 2: 256 x 256, 3 channel, uint8 tiff
  subimage 3: 128 x 128, 3 channel, uint8 tiff
  subimage 4: 64 x 64, 3 channel, uint8 tiff
  subimage 5: 32 x 32, 3 channel, uint8 tiff

```

(continues on next page)

(continued from previous page)

```

subimage 6: 16 x 16, 3 channel, uint8 tiff
subimage 7: 8 x 8, 3 channel, uint8 tiff
subimage 8: 4 x 4, 3 channel, uint8 tiff
subimage 9: 2 x 2, 3 channel, uint8 tiff
subimage 10: 1 x 1, 3 channel, uint8 tiff

$ iinfo -v -a img_6019m.tx
img_6019m.tx : 1024 x 1024, 3 channel, uint8 tiff
  11 subimages: 1024x1024 512x512 256x256 128x128 64x64 32x32 16x16 8x8 4x4 2x2 1x1
subimage 0: 1024 x 1024, 3 channel, uint8 tiff
  channel list: R, G, B
  tile size: 64 x 64
  ...
subimage 1: 512 x 512, 3 channel, uint8 tiff
  channel list: R, G, B
  ...
...

```

13.2 iinfo command-line options

--help

Prints usage information to the terminal.

--version

Prints the version designation of the OIIO library.

-v

Verbose output — prints all metadata of the image files.

-a

Print information about all subimages in the file(s).

-f

Print the filename as a prefix to every line. For example:

```

$ iinfo -v -f img_6019m.jpg

img_6019m.jpg : 1024 x 683, 3 channel, uint8 jpeg
img_6019m.jpg : channel list: R, G, B
img_6019m.jpg : Color space: sRGB
img_6019m.jpg : ImageDescription: "Family photo"
img_6019m.jpg : Make: "Canon"
...

```

-m pattern

Match the *pattern* (specified as an extended regular expression) against data metadata field names and print only data fields whose names match. The default is to print all data fields found in the file (if `-v` is given).

For example:

```
$ iinfo -v -f -m ImageDescription test*.jpg

test3.jpg :      ImageDescription: "Birthday party"
test4.jpg :      ImageDescription: "Hawaii vacation"
test5.jpg :      ImageDescription: "Bob's graduation"
test6.jpg :      ImageDescription: <unknown>
```

Note: the `-m` option is probably not very useful without also using the `-v` and `-f` options.

--hash

Displays a SHA-1 hash of the pixel data of the image (and of each subimage if combined with the `-a` flag).

-s

Show the image sizes, including a sum of all the listed images.

CONVERTING IMAGE FORMATS WITH `ICONVERT`

14.1 Overview

The `iconvert` program will read an image (from any file format for which an `ImageInput` plugin can be found) and then write the image to a new file (in any format for which an `ImageOutput` plugin can be found). In the process, `iconvert` can optionally change the file format or data format (for example, converting floating-point data to 8-bit integers), apply gamma correction, switch between tiled and scanline orientation, or alter or add certain metadata to the image.

The `iconvert` utility is invoked as follows:

```
iconvert options input output
```

Where *input* and *output* name the input image and desired output filename. The image files may be of any format recognized by `OpenImageIO` (i.e., for which `ImageInput` plugins are available). The file format of the output image will be inferred from the file extension of the output filename (e.g., `foo.tif` will write a TIFF file).

Alternately, any number of files may be specified as follows:

```
iconvert --inplace [options] file1 file2 ...
```

When the `--inplace` option is used, any number of file names ≥ 1 may be specified, and the image conversion commands are applied to each file in turn, with the output being saved under the original file name. This is useful for applying the same conversion to many files, or simply if you want to replace the input with the output rather than create a new file with a different name.

14.2 `iconvert` Recipes

This section will give quick examples of common uses of `iconvert`.

14.2.1 Converting between file formats

It's a snap to converting among image formats supported by `OpenImageIO` (i.e., for which `ImageInput` and `ImageOutput` plugins can be found). The `iconvert` utility will simply infer the file format from the file extension. The following example converts a PNG image to JPEG:

```
iconvert lena.png lena.jpg
```

14.2.2 Changing the data format or bit depth

Just use the `-d` option to specify a pixel data format. For example, assuming that `in.tif` uses 16-bit unsigned integer pixels, the following will convert it to an 8-bit unsigned pixels:

```
iconvert -d uint8 in.tif out.tif
```

14.2.3 Changing the compression

The following command converts writes a TIFF file, specifically using zip compression:

```
iconvert --compression zip in.tif out.tif
```

The following command writes its results as a JPEG file at a compression quality of 50 (pretty severe compression), illustrating how some compression methods allow a quality metric to be optionally appended to the name:

```
iconvert --compression jpeg:50 50 big.jpg small.jpg
```

14.2.4 Gamma-correcting an image

The following gamma-corrects the pixels, raising all pixel values to $x^{1/2.2}$ upon writing:

```
iconvert -g 2.2 in.tif out.tif
```

14.2.5 Converting between scanline and tiled images

Convert a scanline file to a tiled file with 16×16 tiles:

```
iconvert --tile 16 16 s.tif t.tif
```

Convert a tiled file to scanline:

```
iconvert --scanline t.tif s.tif
```

14.2.6 Converting images in place

You can use the `--inplace` flag to cause the output to `emph{replace}` the input file, rather than create a new file with a different name. For example, this will re-compress all of your TIFF files to use ZIP compression (rather than whatever they currently are using):

```
iconvert --inplace --compression zip *.tif
```

14.2.7 Change the file modification time to the image capture time

Many image formats (including JPEGs from digital cameras) contain an internal time stamp indicating when the image was captured. But the time stamp on the file itself (what you'd see in a directory listing from your OS) most likely shows when the file was last copied, not when it was created or captured. You can use the following command to re-stamp your files so that the file system modification time matches the time that the digital image was originally captured:

```
iconvert --inplace --adjust-time *.jpg
```

14.2.8 Add captions, keywords, IPTC tags

For formats that support it, you can add a caption/image description, keywords, or arbitrary string metadata:

```
iconvert --inplace --adjust-time --caption "Hawaii vacation" *.jpg

iconvert --inplace --adjust-time --keyword "John" img18.jpg img21.jpg

iconvert --inplace --adjust-time --attrib IPTC:State "HI" \
  --attrib IPTC:City "Honolulu" *.jpg
```

14.3 iconvert command-line options

--help

Prints usage information to the terminal.

-v

Verbose status messages.

--threads n

Use n execution threads if it helps to speed up image operations. The default (also if $n = 0$) is to use as many threads as there are cores present in the hardware.

--inplace

Causes the output to *replace* the input file, rather than create a new file with a different name.

Without this flag, `iconvert` expects two file names, which will be used to specify the input and output files, respectively.

But when `--inplace` option is used, any number of file names ≥ 1 may be specified, and the image conversion commands are applied to each file in turn, with the output being saved under the original file name. This is useful for applying the same conversion to many files.

For example, the following example will add the caption “Hawaii vacation” to all JPEG files in the current directory:

```
iconvert --inplace --adjust-time --caption "Hawaii vacation" *.jpg
```

-d datatype

Attempt to sets the output pixel data type to one of: `UINT8`, `sint8`, `uint16`, `sint16`, `half`, `float`, `double`.

The types `uint10` and `uint12` may be used to request 10- or 12-bit unsigned integers. If the output file format does not support them, `uint16` will be substituted.

If the `-d` option is not supplied, the output data type will be the same as the data format of the input file, if possible.

In any case, if the output file type does not support the requested data type, it will instead use whichever supported data type results in the least amount of precision lost.

-g gamma

Applies a gamma correction of $1/\text{gamma}$ to the pixels as they are output.

--sRGB

Explicitly tags the image as being in sRGB color space. Note that this does not alter pixel values, it only marks which color space those values refer to (and only works for file formats that understand such things). An example use of this command is if you have an image that is not explicitly marked as being in any particular color space, but you know that the values are sRGB.

--tile x y

Requests that the output file be tiled, with the given $x \times y$ tile size, if tiled images are supported by the output format. By default, the output file will take on the tiledness and tile size of the input file.

--scanline

Requests that the output file be scanline-oriented (even if the input file was tile-oriented), if scanline orientation is supported by the output file format. By default, the output file will be scanline if the input is scanline, or tiled if the input is tiled.

--separate

--contig

Forces either “separate” (e.g., RRR...GGG...BBB) or “contiguous” (e.g., RGBRGBRGB...) packing of channels in the file. If neither of these options are present, the output file will have the same kind of channel packing as the input file. Of course, this is ignored if the output file format does not support a choice or does not support the particular choice requested.

--compression method

--compression method:quality

Sets the compression method, and optionally a quality setting, for the output image. Each ImageOutput plugin will have its own set of methods that it supports.

By default, the output image will use the same compression technique as the input image (assuming it is supported by the output format, otherwise it will use the default compression method of the output plugin).

--quality q

Sets the compression quality to q , on a 1–100 floating-point scale. This only has an effect if the particular compression method supports a quality metric (as JPEG does).

DEPRECATED(2.1): This is considered deprecated, and in general we now recommend just appending the quality metric to the `compression name:qual`.

--no-copy-image

Ordinarily, `iconvert` will attempt to use `ImageOutput::copy_image` underneath to avoid de/recompression or alteration of pixel values, unless other settings clearly contradict this (such as any settings that must alter pixel values). The use of `--no-copy-image` will force all pixels to be decompressed, read, and compressed/written, rather than copied in compressed form. We’re not exactly sure when you would need to do this, but we put it in just in case.

--adjust-time

When this flag is present, after writing the output, the resulting file’s modification time will be adjusted to match any “DateTime” metadata in the image. After doing this, a directory listing will show file times that match when the original image was created or captured, rather than simply when `iconvert` was run. This has no effect on image files that don’t contain any “DateTime” metadata.

--caption *text*

Sets the image metadata "ImageDescription". This has no effect if the output image format does not support some kind of title, caption, or description metadata field. Be careful to enclose *text* in quotes if you want your caption to include spaces or certain punctuation!

--keyword *text*

Adds a keyword to the image metadata "Keywords". Any existing keywords will be preserved, not replaced, and the new keyword will not be added if it is an exact duplicate of existing keywords. This has no effect if the output image format does not support some kind of keyword field.

Be careful to enclose *text* in quotes if you want your keyword to include spaces or certain punctuation. For image formats that have only a single field for keywords, OpenImageIO will concatenate the keywords, separated by semicolon (;), so don't use semicolons within your keywords.

--clear-keywords

Clears all existing keywords in the image.

--attrib *text*

Sets the named image metadata attribute to a string given by *text*. For example, you could explicitly set the IPTC location metadata fields with:

```
iconvert --attrib "IPTC:City" "Berkeley" in.jpg out.jpg
```

--orientation *orient*

Explicitly sets the image's "Orientation" metadata to a numeric value (see [Display hints](#) for the numeric codes). This only changes the metadata field that specifies how the image should be displayed, it does NOT alter the pixels themselves, and so has no effect for image formats that don't support some kind of orientation metadata.

--rotcw**--rotccw****--rot180**

Adjusts the image's "Orientation" metadata by rotating it 90° clockwise, 90° degrees counter-clockwise, or 180°, respectively, compared to its current setting. This only changes the metadata field that specifies how the image should be displayed, it does NOT alter the pixels themselves, and so has no effect for image formats that don't support some kind of orientation metadata.

SEARCHING IMAGE METADATA WITH IGREP

The `igrep` program search one or more image files for metadata that match a string or regular expression.

15.1 Using `igrep`

The `igrep` utility is invoked as follows:

```
igrep [options] pattern filename ...
```

Where *pattern* is a POSIX.2 regular expression (just like the Unix/Linux `grep(1)` command), and *filename* (and any following names) specify images or directories that should be searched. An image file will “match” if any of its metadata contains values contain substring that are recognized regular expression. The image files may be of any format recognized by OpenImageIO (i.e., for which ImageInput plugins are available).

Example:

```
$ igrep Jack *.jpg
bar.jpg: Keywords = Carly; Jack
foo.jpg: Keywords = Jack
test7.jpg: ImageDescription = Jack on vacation
```

15.2 `igrep` command-line options

--help

Prints usage information to the terminal.

--version

Prints the version designation of the OIIO library.

-d

Print directory names as it recurses. This only happens if the `-r` option is also used.

-E

Interpret the pattern as an extended regular expression (just like `egrep` or `grep -E`).

-f

Match the expression against the filename, as well as the metadata within the file.

-i

Ignore upper/lower case distinctions. Without this flag, the expression matching will be case-sensitive.

-l

Simply list the matching files by name, suppressing the normal output that would include the metadata name and values that matched. For example:

```
$ igrep Jack *.jpg
bar.jpg: Keywords = Carly; Jack
foo.jpg: Keywords = Jack
test7.jpg: ImageDescription = Jack on vacation

$ igrep -l Jack *.jpg
bar.jpg
foo.jpg
test7.jpg
```

-r

Recurse into directories. If this flag is present, any files specified that are directories will have any image file contained therein to be searched for a match (and so on, recursively).

-v

Invert the sense of matching, to select image files that *do not* match the expression.

COMPARING IMAGES WITH IDIFF

16.1 Overview

The `idiff` program compares two images, printing a report about how different they are and optionally producing a third image that records the pixel-by-pixel differences between them. There are a variety of options and ways to compare (absolute pixel difference, various thresholds for warnings and errors, and also an optional perceptual difference metric).

Because `idiff` is built on top of OpenImageIO, it can compare two images of any formats readable by ImageInput plugins on hand. They may have any (or different) file formats, data formats, etc.

16.2 Using `idiff`

The `idiff` utility is invoked as follows:

```
idiff [options] input1 input2|directory
```

Where *input1* and *input2* are the names of two image files that should be compared. They may be of any format recognized by OpenImageIO (i.e., for which image-reading plugins are available).

When a *directory* is specified instead of *input2* then `idiff` will use the same-named file as *input1* in the specified directory.

If the two input images are not the same resolutions, or do not have the same number of channels, the comparison will return FAILURE immediately and will not attempt to compare the pixels of the two images. If they are the same dimensions, the pixels of the two images will be compared, and a report will be printed including the mean and maximum error, how many pixels were above the warning and failure thresholds, and whether the result is PASS, WARNING, or FAILURE. For example:

```
$ idiff a.jpg b.jpg

Comparing "a.jpg" and "b.jpg"
  Mean error = 0.00450079
  RMS error = 0.00764215
  Peak SNR = 42.3357
  Max error = 0.254902 @ (700, 222, B)
  574062 pixels (82.1%) over 1e-06
  574062 pixels (82.1%) over 1e-06
FAILURE
```

The “mean error” is the average difference (per channel, per pixel). The “max error” is the largest difference in any pixel channel, and will point out on which pixel and channel it was found. It will also give a count of how many pixels were above the warning and failure thresholds.

The metadata of the two images (e.g., the comments) are not currently compared; only differences in pixel values are taken into consideration.

16.2.1 Raising the thresholds

By default, if any pixels differ between the images, the comparison will fail. You can allow *some* differences to still pass by raising the failure thresholds. The following example will allow images to pass the comparison test, as long as no more than 10% of the pixels differ by 0.004 (just above a 1/255 threshold):

```
idiff -fail 0.004 -failpercent 10 a.jpg b.jpg
```

But what happens if a just a few pixels are very different? Maybe you want that to fail, also. The following adjustment will fail if at least 10% of pixels differ by 0.004, or if *any* pixel differs by more than 0.25:

```
idiff -fail 0.004 -failpercent 10 -hardfail 0.25 a.jpg b.jpg
```

If none of the failure criteria are met, and yet some pixels are still different, it will still give a WARNING. But you can also raise the warning threshold in a similar way:

```
idiff -fail 0.004 -failpercent 10 -hardfail 0.25 \  
      -warn 0.004 -warnpercent 3 a.jpg b.jpg
```

The above example will PASS as long as fewer than 3% of pixels differ by more than 0.004. If it does, it will be a WARNING as long as no more than 10% of pixels differ by 0.004 and no pixel differs by more than 0.25, otherwise it is a FAILURE.

16.2.2 Output a difference image

Ordinary text output will tell you how many pixels failed or were warnings, and which pixel had the biggest difference. But sometimes you need to see visually where the images differ. You can get `idiff` to save an image of the differences between the two input images:

```
idiff -o diff.tif -abs a.jpg b.jpg
```

The `-abs` flag saves the absolute value of the differences (i.e., all positive values or zero). If you omit the `-abs`, pixels in which `a.jpg` have smaller values than `b.jpg` will be negative in the difference image (be careful in this case of using a file format that doesn't support negative values).

You can also scale the difference image with the `-scale`, making them easier to see. And the `-od` flag can be used to output a difference image only if the comparison fails, but not if the images pass within the designated threshold (thus saving you the trouble and space of saving a black image).

16.3 `idiff` Command Line Argument Reference

The various command-line options are discussed below:

16.3.1 General options

--help

Prints usage information to the terminal.

--version

Prints the version designation of the OIIO library.

-v

Verbose output — more detail about what it finds when comparing images, even when the comparison does not fail.

-q

Quiet mode – output nothing for successful match), output only minimal error messages to stderr for failure / no match. The shell return code also indicates success or failure (successful match returns 0, failure returns nonzero).

-a

Compare all subimages. Without this flag, only the first subimage of each file will be compared.

16.3.2 Thresholds and comparison options

-fail A

-failrelative R

-failpercent P

-hardfail H

Sets the threshold for FAILURE: if more than P % of pixels (on a 0-100 floating point scale) are greater than A different absolutely or R relatively (to the mean of the two values), or if *any* pixels are more than H different absolutely. The defaults are to fail if more than 0% (any) pixels differ by more than 0.00001 (1e-6), and H is infinite.

-warn A

-warnrelative R

-warnpercent P

-hardwarn H

Sets the threshold for WARNING: if more than P % of pixels (on a 0-100 floating point scale) are greater than A different absolutely or R different relatively (to the mean of the two values), or if *any* pixels are more than H different absolutely. The defaults are to warn if more than 0% (any) pixels differ by more than 0.00001 (1e-6), and H is infinite.

--allowfailures N

Allows up to N pixels to differ by any amount, and still consider it a matching image.

This option was added in OIIO 2.3.19.

-p

Does an additional test on the images to attempt to see if they are *perceptually* different (whether you are likely to discern a difference visually), using Hector Yee's metric. If this option is enabled, the statistics will additionally show a report on how many pixels failed the perceptual test, and the test overall will fail if more than the "fail percentage" failed the perceptual test.

16.3.3 Difference image output

-o outfile

Outputs a *difference image* to the designated file. This difference image pixels consist are each of the value of the corresponding pixel from *image1* minus the value of the pixel *image2*.

The file extension of the output file is used to determine the file format to write (e.g., `out.tif` will write a TIFF file, `out.jpg` will write a JPEG, etc.). The data format of the output file will be format of whichever of the two input images has higher precision (or the maximum precision that the designated output format is capable of, if that is less than either of the input images).

Note that pixels whose value is lower in *image1* than in *image2*, this will result in negative pixels (which may be clamped to zero if the image format does not support negative values)), unless the `-abs` option is also used.

-abs

Will cause the output image to consist of the *absolute value* of the difference between the two input images (so all values in the difference image ≥ 0).

-scale factor

Scales the values in the difference image by the given (floating point) factor. The main use for this is to make small actual differences more visible in the resulting difference image by giving a large scale factor.

-od

Causes a difference image to be produce *only* if the image comparison fails. That is, even if the `-o` option is used, images that are within the comparison threshold will not write out a useless black (or nearly black) difference image.

16.3.4 Process return codes

The `idiff` program will return a code that can be used by scripts to indicate the results:

0	OK: the images match within the warning and error thresholds.
1	Warning: the errors differ a little, but within error thresholds.
2	Failure: the errors differ a lot, outside error thresholds.
3	The images weren't the same size and couldn't be compared.
4	File error: could not find or open input files, etc.

MAKING TILED MIP-MAP TEXTURE FILES WITH MAKETX OR OIIOTOOL

17.1 Overview

The TextureSystem (Chapter *Texture Access: TextureSystem*) will exhibit much higher performance if the image files it uses as textures are tiled (versus scanline) orientation, have multiple subimages at different resolutions (MIP-mapped), and include a variety of header or metadata fields appropriately set for texture maps. Any image that you intend to use as input to TextureSystem, therefore, should first be converted to have these properties. An ordinary image will work as a texture, but without this additional step, it will be drastically less efficient in terms of memory, disk or network I/O, and time.

This can be accomplished programmatically using the ImageBufAlgo `make_texture()` function (see Section *Import / export* for C++ and Section *Import / export* for Python).

OpenImageIO includes two command-line utilities capable of converting ordinary images into texture files: **maketx** and **oiio tool**.¹

17.2 maketx

The **maketx** program will convert ordinary images to efficient textures. The **maketx** utility is invoked as follows:

```
maketx [options] input... -o output
```

Where *input* and *output* name the input image and desired output filename. The input files may be of any image format recognized by OpenImageIO (i.e., for which ImageInput plugins are available). The file format of the output image will be inferred from the file extension of the output filename (e.g., `foo.tif` will write a TIFF file).

Command-line arguments are:

--help

Prints usage information to the terminal.

--version

Prints the version designation of the OIIO library.

-v

Verbose status messages, including runtime statistics and timing.

--runstats

Print runtime statistics and timing.

¹ Why are there two programs? Historical artifact – **maketx** existed first, and much later **oiio tool** was extended to be capable of directly writing texture files. If you are simply converting an image into a texture, **maketx** is more straightforward and foolproof, in that you can't accidentally forget to turn it into a texture, as you might do with and much later **oiio tool** was extended to be capable of directly writing texture files.

-o *outputname*

Sets the name of the output texture.

--threads *<n>*

Use *n* execution threads if it helps to speed up image operations. The default (also if *n*=0) is to use as many threads as there are cores present in the hardware.

--format *<formatname>*

Specifies the image format of the output file (e.g., “tiff”, “OpenEXR”, etc.). If **--format** is not used, **maketx** will guess based on the file extension of the output filename; if it is not a recognized format extension, TIFF will be used by default.

-d *<datatype>*

Attempt to sets the output pixel data type to one of: `UINT8`, `sint8`, `uint16`, `sint16`, `half`, `float`, `double`.

If the **-d** option is not supplied, the output data type will be the same as the data format of the input file.

In either case, the output file format itself (implied by the file extension of the output filename) may trump the request if the file format simply does not support the requested data type.

--tile *<x>* *<y>*

Specifies the tile size of the output texture. If not specified, **maketx** will make 64 x 64 tiles.

--separate

Forces “separate” (e.g., RRR...GGG...BBB) packing of channels in the output file. Without this option specified, “contiguous” (e.g., RGBRGBRGB...) packing of channels will be used for those file formats that support it.

--compression *<method>*

--compression *<method:quality>*

Sets the compression method, and optionally a quality setting, for the output image (the default is to try to use “zip” compression, if it is available).

-u

Ordinarily, textures are created unconditionally (which could take several seconds for large input files if read over a network) and will be stamped with the current time.

The **-u** option enables *update mode*: if the output file already exists, and has the same time stamp as the input file, and the command-line arguments that created it are identical to the current ones, then the texture will be left alone and not be recreated. If the output file does not exist, or has a different time stamp than the input file, or was created using different command line arguments, then the texture will be created and given the time stamp of the input file.

--wrap *<wrapmode>*

--swrap *<wrapmode>*, **--twrap** *<wrapmode>*

Sets the default *wrap mode* for the texture, which determines the behavior when the texture is sampled outside the [0,1] range. Valid wrap modes are: `black`, `clamp`, `periodic`, `mirror`. The default, if none is set, is `black`. The **--wrap** option sets the wrap mode in both directions simultaneously, while the **--swrap** and **--twrap** may be used to set them individually in the *s* (horizontal) and *t* (vertical) directions.

Although this sets the default wrap mode for a texture, note that the wrap mode may have an override specified in the texture lookup at runtime.

--resize

Causes the highest-resolution level of the MIP-map to be a power-of-two resolution in each dimension (by rounding up the resolution of the input image). There is no good reason to do this for the sake of OIIO’s texture system, but some users may require it in order to create MIP-map images that are compatible with both OIIO and other texturing systems that require power-of-2 textures.

--filter <name>

By default, the resizing step that generates successive MIP levels uses a triangle filter to bilinearly combine pixels (for MIP levels with even number of pixels, this is also equivalent to a box filter, which merely averages groups of 4 adjacent pixels). This is fast, but for source images with high frequency content, can result in aliasing or other artifacts in the lower-resolution MIP levels.

The **--filter** option selects a high-quality filter to use when resizing to generate successive MIP levels. Choices include **lanczos3** (our best recommendation for highest-quality filtering, a 3-lobe Lanczos filter), **box**, **triangle**, **catrom**, **blackman-harris**, **gaussian**, **mitschell**, **bspline**, **cubic**, **keys**, **simon**, **rifman**, **radial-lanczos3**, **disk**, **sinc**.

If you select a filter with negative lobes (including **lanczos3**, **sinc**, **lanczos3**, **keys**, **simon**, **rifman**, or **catrom**), and your source image is an HDR image with very high contrast regions that include pixels with values >1 , you may also wish to use the **--rangecompress** option to avoid ringing artifacts.

--hicomp

Perform highlight compensation. When HDR input data with high-contrast highlights is turned into a MIP-mapped texture using a high-quality filter with negative lobes (such as **lanczos3**), objectionable ringing could appear near very high-contrast regions with pixel values >1 . This option improves those areas by using range compression (transforming values from a linear to a logarithmic scale that greatly compresses the values >1) prior to each image filtered-resize step, and then expanded back to a linear format after the resize, and also clamping resulting pixel values to be non-negative. This can result in some loss of energy, but often this is a preferable alternative to ringing artifacts in your upper MIP levels.

--sharpen <contrast>

EXPERIMENTAL: USE AT YOUR OWN RISK!

This option will run an additional sharpening filter when creating the successive MIP-map levels. It uses an unsharp mask (much like in Section sec-iba-unsharpmask) to emphasize high-frequency details to make features “pop” visually even at high MIP-map levels. The *contrast* controls the degree to which it does this. Probably a good value to enhance detail but not go overboard is 0.5 or even 0.25. A value of 1.0 may make strange artifacts at high MIP-map levels. Also, if you simultaneously use **--filter unsharp-median**, a slightly different variant of unsharp masking will be used that employs a median filter to separate out the low-frequencies, this may tend to help emphasize small features while not over-emphasizing large edges.

--nomipmap

Causes the output to *not* be MIP-mapped, i.e., only will have the highest-resolution level.

--nchannels <n>

Sets the number of output channels. If *n* is less than the number of channels in the input image, the extra channels will simply be ignored. If *n* is greater than the number of channels in the input image, the additional channels will be filled with 0 values.

--chnames a,b,...

Renames the channels of the output image. All the channel names are concatenated together, separated by commas. A “blank” entry will cause the channel to retain its previous value (for example, **--chnames ,,,A** will rename channel 3 to be “A” and leave channels 0-2 as they were).

--checknan

Checks every pixel of the input image to ensure that no NaN or Inf values are present. If such non-finite pixel values are found, an error message will be printed and **maketx** will terminate without writing the output image (returning an error code).

--fixnan strategy

Repairs any pixels in the input image that contained NaN or Inf values (hereafter referred to collectively as “nonfinite”). If *strategy* is **black**, nonfinite values will be replaced with 0. If *strategy* is **box3**, nonfinite values will be replaced by the average of all the finite values within a 3x3 region surrounding the pixel.

--fullpixels

Resets the “full” (or “display”) pixel range to be the “data” range. This is used to deal with input images that appear, in their headers, to be crop windows or overscanned images, but you want to treat them as full 0–1 range images over just their defined pixel data.

--Mcamera <...16 floats...>**--Mscreen <...16 floats...>**

Sets the camera and screen matrices (sometimes called N1 and NP, respectively, by some renderers) in the texture file, overriding any such matrices that may be in the input image (and would ordinarily be copied to the output texture).

--prman-metadata

Causes metadata “PixarTextureFormat” to be set, which is useful if you intend to create an OpenEXR texture or environment map that can be used with PRMan as well as OIIO.

--attrib <name> <value>

Adds or replaces metadata with the given *name* to have the specified *value*.

It will try to infer the type of the metadata from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as `int` metadata; if it also contains a decimal point, it will be saved as `float` metadata; otherwise, it will be saved as a `string` metadata.

For example, you could explicitly set the IPTC location metadata fields with:

```
oiiotool --attrib "IPTC:City" "Berkeley" in.jpg out.jpg
```

--sattrib <name> <value>

Adds or replaces metadata with the given *name* to have the specified *value*, forcing it to be interpreted as a `string`. This is helpful if you want to set a `string` metadata to a value that the `--attrib` command would normally interpret as a number.

--sansattrib

When set, this edits the command line inserted in the “Software” and “ImageHistory” metadata to omit any verbose `--attrib` and `--sattrib` commands.

--constant-color-detect

Detects images in which all pixels are identical, and outputs the texture at a reduced resolution equal to the tile size, rather than filling endless tiles with the same constant color. That is, by substituting a low-res texture for a high-res texture if it’s a constant color, you could save a lot of save disk space, I/O, and texture cache size. It also sets the “ImageDescription” to contain a special message of the form `ConstantColor=[r,g,...]`.

--monochrome-detect

Detects multi-channel images in which all color components are identical, and outputs the texture as a single-channel image instead. That is, it changes RGB images that are gray into single-channel gray scale images.

--opaque-detect

Detects images that have a designated alpha channel for which the alpha value for all pixels is 1.0 (fully opaque), and omits the alpha channel from the output texture. So, for example, an RGBA input texture where A=1 for all pixels will be output just as RGB. The purpose is to save disk space, texture I/O bandwidth, and texturing time for those textures where alpha was present in the input, but clearly not necessary.

--ignore-unassoc

Ignore any header tags in the input images that indicate that the input has “unassociated” alpha. When this option is used, color channels with unassociated alpha will not be automatically multiplied by alpha to turn them into associated alpha. This is also a good way to fix input images that really are associated alpha, but whose headers incorrectly indicate that they are unassociated alpha.

--prman

PRMan is will crash in strange ways if given textures that don't have its quirky set of tile sizes and other specific metadata. If you want **maketx** to generate textures that may be used with either OpenImageIO or PRMan, you should use the **--prman** option, which will set several options to make PRMan happy, overriding any contradictory settings on the command line or in the input texture.

Specifically, this option sets the tile size (to 64x64 for 8 bit, 64x32 for 16 bit integer, and 32x32 for float or half images), uses "separate" planar configuration (**--separate**), and sets PRMan-specific metadata (**--prman-metadata**). It also outputs sint16 textures if uint16 is requested (because PRMan for some reason does not accept true uint16 textures), and in the case of TIFF files will omit the Exif directory block which will not be recognized by the older version of libtiff used by PRMan.

OpenImageIO will happily accept textures that conform to PRMan's expectations, but not vice versa. But OpenImageIO's TextureSystem has better performance with textures that use **maketx**'s default settings rather than these oddball choices. You have been warned!

--oiio

This sets several options that we have determined are the optimal values for OpenImageIO's TextureSystem, overriding any contradictory settings on the command line or in the input texture.

Specifically, this is the equivalent to using

```
--separate --tile 64 64
```

--colorconvert <inspace> <outspace>

Convert the color space of the input image from *inspace* to *ospace*. If OpenColorIO is installed and finds a valid configuration, it will be used for the color conversion. If OCIO is not enabled (or cannot find a valid configuration, OIIO will at least be able to convert among linear, sRGB, and Rec709.

--colorconfig <name>

Explicitly specify a custom OpenColorIO configuration file. Without this, the default is to use the \$OCIO environment variable as a guide for the location of the OpenColorIO configuration file.

--unpremult

When undergoing some color conversions, it is helpful to "un-premultiply" the alpha before converting color channels, and then re-multiplying by alpha. Caveat emptor – if you don't know exactly when to use this, you probably shouldn't be using it at all.

--mipimage <filename>

Specifies the name of an image file to use as a custom MIP-map level, instead of simply downsizing the last one. This option may be used multiple times to specify multiple levels. For example:

```
maketx 256.tif --mipimage 128.tif --mipimage 64.tif -o out.tx
```

This will make a texture with the first MIP level taken from 256.tif, the second level from 128.tif, the third from 64.tif, and then subsequent levels will be the usual downsizings of 64.tif.

--envlatl

Creates a latitude-longitude environment map, rather than an ordinary texture map.

--lightprobe

Creates a latitude-longitude environment map, but in contrast to **--envlatl**, the original input image is assumed to be formatted as a *light probe* image. (See <http://www.pauldebevec.com/Probes/> for examples and an explanation of the geometric layout.)

--bumpslopes

For a single channel input image representing height (that you would ordinarily use for a bump or displacement),

this produces a 6-channel texture that contains the first and second moments of bump slope, which can be used to implement certain bump-to-roughness techniques. The channel layout is as follows:

index	channel name	data at MIP level 0
0	b0_h	h (height)
1	b1_dhds	$\partial h / \partial s$
2	b2_dhdt	$\partial h / \partial t$
3	b3_dhds2	$(\partial h / \partial s)^2$
4	b4_dhdt2	$(\partial h / \partial t)^2$
5	b5_dhdsdt	$(\partial h / \partial s) \cdot (\partial h / \partial t)$

(The strange channel names are to guarantee they are in alphabetical order, to prevent reordering by OpenEXR. And also note that the simple relationships between channels 1 & 2, and 3-6, is only for the highest- resolution level of the MIP-map, and will differ for the lower-res filtered versions, and those differences is what gives us the slope momets that we need.)

A reference for explaining how this can be used is here:

Christophe Hery, Michael Kass, and Junhi Ling. “Geometry into Shading.” Technical Memo 14-04, Pixar Animation Studios, 2014. <https://graphics.pixar.com/library/BumpRoughness>

--bumpformat <bformat>

In conjunction with **--bumpslopes**, this option can specify the strategy for determining whether a 3-channel source image specifies a height map or a normal map. The value “height” indicates it is a height map (only the first channel will be used). The value “normal” indicates it is a normal map (all three channels will be used for x, y, z). The default value, “auto”, indicates that it should be interpreted as a height map if and only if the R, G, B channel values are identical in all pixels, otherwise it will be interpreted as a 3-channel normal map.

--uvslopes_scale <scalefactor>

Used in conjunction with **--bumpslopes**, this computes derivatives for the bumpslopes data in UV space rather than in texel space, and divides them by a scale factor. If the value is 0 (default), this is disabled. For a nonzero value, it will be the scale factor. If you use this feature, a suggested value is 256.

(This option was added for OpenImageIO 2.3.)

--cdf

--cdfsigma <SIGMA>

--cdfbits <BITS>

When **--cdf** is used, the output texture will write a Gaussian CDF and Inverse Gaussian CDF as per-channel metadata in the texture, which can be used by shaders to implement Histogram-Preserving Blending. This is only useful when the texture being created is written to an image format that supports arbitrary metadata (e.g. OpenEXR).

When **--cdf** has been enabled, the additional options **--cdfsigma** may be used to specify the CDF sigma value (defaulting to 1.0/6.0), and **--cdfbits** specifies the number of bits to use for the size of the CDF table (defaulting to 8, which means 256 bins).

- Benedikt Bitterli <https://benedikt-bitterli.me/histogram-tiling/>

These options were first added in OpenImageIO 2.3.10.

--handed <value>

Adds a “handed” metadata to the resulting texture, which reveals the handedness of vector displacement maps or normal maps, when expressed in tangent space. Possible values are `left` or `right`.

This option was first added in OpenImageIO 2.4.0.2.

17.3 oiiotool

The **oiiotool** utility (Chapter *oiiotool: the OIO Swiss Army Knife*) is capable of writing textures using the `-otex` option, lat-long environment maps using the `-oenv` option, and bump/normal maps that include normal distribution moments. Roughly speaking,

```
maketx [maketx-options] input -o output
maketx -envlatl [maketx-options] input -o output
maketx -bumpslopes [maketx-options] input -o output
```

are equivalent to, respectively,

```
oiiotool input [oiiotool-options] -otex output
oiiotool input [oiiotool-options] -oenv output
oiiotool input [oiiotool-options] -obump output
```

However, the notation for the various options are not identical between the two programs, as will be explained by the remainder of this section.

The most important difference between **oiiotool** and **maketx** is that **oiiotool** can do so much more than convert an existing input image to a texture – literally any image creation or manipulation you can do via **oiiotool** may be output directly as a full texture file using `-otex` (or as a lat-long environment map using `-oenv`).

Note that it is vitally important that you use one of the texture output commands (`-otex` or `-oenv`) when creating textures with **oiiotool** — if you inadvertently forget and use an ordinary `-o`, you will end up with an output image that is much less efficient to use as a texture.

17.3.1 Command line arguments useful when creating textures

As with any use of **oiiotool**, you may use the following to control the run generally:

--help**-v****--runstats****--threads <n>**

and as with any use of **oiiotool**, you may use the following command-line options to control aspects of the any output files (including those from `-otex` and `-oenv`, as well as `-o`). Only brief descriptions are given below, please consult Chapter *oiiotool* for detailed explanations.

-d <datatype>

Specify the pixel data type (`UINT8`, `uint16`, `half`, `float`, etc.) if you wish to override the default of writing the same data type as the first input file read.

--tile <x> <y>

Explicitly override the tile size (though you are strongly urged to use the default, and not use this command).

--compression <method>

Explicitly override the default compression methods when writing the texture file.

--ch <channellist>

Shuffle, add, delete, or rename channels (see `sec-oiitool-ch`).

--chnames a,b,...

Renames the channels of the output image.

--fixnan <strategy>

Repairs any pixels in the input image that contained NaN or Inf values (if the *strategy* is `box3` or `black`), or to simply abort with an error message (if the *strategy* is `error`).

--fullpixels

Resets the “full” (or “display”) pixel range to be the “data” range.

--planarconfig separate

Forces “separate” (e.g., RRR...GGG...BBB) packing of channels in the output texture. This is almost always a bad choice, unless you know that the texture file must be readable by PRMan, in which case it is required.

--attrib <name> <value>

oiitool’s `--attrib` command may be used to set attributes in the metadata of the output texture.

--attrib:type=matrix worldtocam <...16 comma-separated floats...>**--attrib:type=matrix** screentocam <...16 comma-separated floats...>

Set/override the camera and screen matrices.

17.3.2 Optional arguments to `-otex`, `-oenv`, `-obump`

As with many **oiitool** commands, the `-otex` and `-oenv` may have various optional arguments appended, in the form `:name=value` (see Section `sec-oiitooloptionalargs`).

Optional arguments supported by `-otex` and `-oenv` include all the same options as `-o` (Section [Writing images](#)) and also the following (explanations are brief, please consult Section `sec-maketx` for more detailed explanations of each, for the corresponding **maketx** option):

Appended Option	maketx equivalent
<code>wrap= string</code>	<code>--wrap</code>
<code>swrap= string</code>	<code>--swrap</code>
<code>twrap= string</code>	<code>--twrap</code>
<code>resize=1</code>	<code>--resize</code>
<code>nomipmap=1</code>	<code>--nomipmap</code>
<code>updatemode=1</code>	<code>-u</code>
<code>monochrome_detect=1</code>	<code>--monochrome-detect</code>
<code>opaque_detect=1</code>	<code>--opaque-detect</code>
<code>unpremult=1</code>	<code>--unpremult</code>
<code>incolospace= name</code>	<code>--incolospace</code>
<code>outcolospace= name</code>	<code>--outcolospace</code>
<code>highlightcomp=1</code>	<code>--hicomp</code>
<code>sharpen= float</code>	<code>--sharpen</code>
<code>filter= string</code>	<code>--filter</code>
<code>bumpformat= string</code>	<code>--bumpformat</code>
<code>uvslopes_scale= float</code>	<code>--uvslopes-scale</code>
<code>prman_metadata=1</code>	<code>--prman</code>
<code>prman_options=1</code>	<code>--prman-metadata</code>

17.3.3 Examples

```
oiiotool in.tif -otex out.tx
```

```
oiiotool in.jpg --colorconvert sRGB linear -d uint16 -otex out.tx
```

```
oiiotool --pattern:checker 512x512 3 -d uint8 -otex:wrap=periodic checker.tx
```

```
oiiotool in.exr -otex:highlightcomp=1:sharpen=0.5 out.exr
```

METADATA CONVENTIONS

The `ImageSpec` class, described thoroughly in *Image Specification: ImageSpec*, provides the basic description of an image that are essential across all formats — resolution, number of channels, pixel data format, etc. Individual images may have additional data, stored as name/value pairs in the `extra_attribs` field. Though literally *anything* can be stored in `extra_attribs` — it's specifically designed for format- and user-extensibility — this chapter establishes some guidelines and lays out all of the field names that `OpenImageIO` understands.

18.1 Description of the image

"ImageDescription" : string

The image description, title, caption, or comments.

"Keywords" : string

Semicolon-separated keywords describing the contents of the image. (Semicolons are used rather than commas because of the common case of a comma being part of a keyword itself, e.g., "Kurt Vonnegut, Jr." or "Washington, DC.")

"Artist" : string

The artist, creator, or owner of the image.

"Copyright" : string

Any copyright notice or owner of the image.

"DateTime" : string

The creation date of the image, in the following format: `YYYY:MM:DD HH:MM:SS` (exactly 19 characters long, not including a terminating `NULL`). For example, 7:30am on Dec 31, 2008 is encoded as `"2008:12:31 07:30:00"`.

Usually this is simply the time that the image data was last modified. It may be wise to also store the `"Exif:DateTimeOriginal"` and `"Exif:DateTimeDigitized"` (see Section *Exif metadata*) to further distinguish the original image and its conversion to digital media.

"DocumentName" : string

The name of an overall document that this image is a part of.

"Software" : string

The software that was used to create the image.

"HostComputer" : string

The name or identity of the computer that created the image.

18.2 Display hints

"Orientation" : int

By default, image pixels are ordered from the top of the display to the bottom, and within each scanline, from left to right (i.e., the same ordering as English text and scan progression on a CRT). But the "Orientation" field can suggest that it should be displayed with a different orientation, according to the TIFF/EXIF conventions:

1	normal (top to bottom, left to right)
2	flipped horizontally (top to bottom, right to left)
3	rotated 180° (bottom to top, right to left)
4	flipped vertically (bottom to top, left to right)
5	transposed (left to right, top to bottom)
6	rotated 90° clockwise (right to left, top to bottom)
7	transverse (right to left, bottom to top)
8	rotated 90° counter-clockwise (left to right, bottom to top)

"PixelAspectRatio" : float

The aspect ratio (x/y) of the size of individual pixels, with square pixels being 1.0 (the default).

"XResolution" : float

"YResolution" : float

"ResolutionUnit" : string

The number of horizontal (x) and vertical (y) pixels per resolution unit. This ties the image to a physical size (where applicable, such as with a scanned image, or an image that will eventually be printed).

Different file formats may dictate different resolution units. For example, the TIFF ImageIO plugin supports none, in, and cm.

"oio:Movie" : int

If nonzero, a hint that a multi-image file is meant to be interpreted as an animation (i.e., that the subimages are a time sequence).

"oio:subimages" : int

If nonzero, the number of subimages in the file. Not all image file formats can know this without reading the entire file, and in such cases, this attribute will not be set or will be 0. If the value is present and greater than zero, it can be trusted, but if not, nothing should be inferred and you will have to repeatedly seek to subimages to find out how many there are.

"FramesPerSecond" : rational

For a multi-image file intended to be played back as an animation, the frame refresh rate. (It's technically a rational, but it may be retrieved as a float also, if you are ok with imprecision.)

18.3 Color information

"oio:ColorSpace" : string

The name of the color space of the color channels. Values include:

- **"scene_linear"** : Color pixel values are known to be scene-linear and using facility-default color primaries as defined by the OpenColorIO configuration. Note that **"linear"** is treated as a synonym. (Note: when no color config is found, this are presumed to use sRGB/Rec709 color primaries when built against OpenColorIO 2.1 or earlier, or when no OCIO support is available, but is presumed to be ACEScg when built against OCIO 2.2 or higher and using its built-in config.)

- "lin_srgb" : Color pixel values are known to be linear and using sRGB/Rec709 color primaries.
- "sRGB" : Using standard sRGB response and primaries.
- "Rec709" : Using standard Rec709 response and primaries.
- "ACEScg" : ACEScg color space encoding.
- "AdobeRGB" : Adobe RGB color space.
- "KodakLog" : Kodak logarithmic color space.
- "GammaX.Y" : Color values have been gamma corrected (raised to the power $1/\gamma$). The X.Y is the numeric value of the gamma exponent.
- *arbitrary* : The name of any color space known to OpenColorIO (if OCIO support is present).

"oiio:Gamma" : float

If the color space is "GammaX.Y", this value is the gamma exponent. (Optional/deprecated; if present, it should match the suffix of the color space.)

"oiio:BorderColor" : float[nchannels]

The color presumed to be filling any parts of the display/full image window that are not overlapping the pixel data window. If not supplied, the default is black (0 in all channels).

"ICCProfile" : uint8[]

"ICCProfile:...various..." : ...various types...

The ICC color profile takes the form of an array of bytes (unsigned 8 bit chars) whose contents and format is as dictated by the ICC specification. The length of the array is the length of the profile blob.

When reading images containing ICC profiles, there may be a number of other attributes extracted from the ICC profile (such as `ICCProfile:device_class`). These are for informational convenience only, as they replicate information which is also in the ICCProfile byte array. Be aware that *setting* these attributes will not result in modifying the ICC profile byte array ("ICCProfile"), which is considered the sole piece of durable ICC profile information.

18.4 Disk file format info/hints

"oiio:BitsPerSample" : int

Number of bits per sample *in the file*.

Note that this may not match the reported `ImageSpec::format`, if the plugin is translating from an unsupported format. For example, if a file stores 4 bit grayscale per channel, the "oiio:BitsPerSample" may be 4 but the `format` field may be `TypeDesc::UINT8` (because the OpenImageIO APIs do not support fewer than 8 bits per sample).

"oiio:UnassociatedAlpha" : int

Whether the data in the file stored alpha channels (if any) that were unassociated with the color (i.e., color not "premultiplied" by the alpha coverage value).

"planarconfig" : string

`contig` indicates that the file has contiguous pixels (RGB RGB RGB...), whereas `separate` indicate that the file stores each channel separately (RRR...GGG...BBB...).

Note that only contiguous pixels are transmitted through the OpenImageIO APIs, but this metadata indicates how it is (or should be) stored in the file, if possible.

"compression" : string

Indicates the type of compression the file uses. Supported compression modes will vary from file format to file format, and each reader/writer plugin should document the modes it supports. If `ImageOutput::open` is called with an `ImageSpec` that specifies an compression mode not supported by that `ImageOutput`, it will choose a reasonable default. As an example, the `OpenEXR` writer supports `none`, `rle`, `zip`, `zips`, `piz`, `pxr24`, `b44`, `b44a`, `dwaab`, or `dwab`.

he compression name is permitted to have a quality value to be appended fter a colon, for example `dwaab:60`. The exact meaning and range of he quality value can vary between different file formats and compression odes, and some don't support quality values at all (it will be ignored if ot supported, or if out of range).

"CompressionQuality" : int

DEPRECATED(2.1)

This is a deprecated methods of separately specifying the compression quality. Indicates the quality of compression to use (0–100), for those plugins and compression methods that allow a variable amount of compression, with higher numbers indicating higher image fidelity.

18.5 Substituting an IOProxy for custom I/O overrides

Format readers and writers that respond positively to `supports("ioproxy")` have the ability to read or write using an *I/O proxy* object. Among other things, this lets an `ImageOutput` write the file to a memory buffer rather than saving to disk, and for an `ImageInput` to read the file from a memory buffer. This behavior is controlled by a special attributes

"oio:ioproxy" : pointer

Pointer to a `Filesystem::IOProxy` that will handle the I/O.

An explanation of how this feature is used may be found in Sections *Custom I/O proxies (and reading the file from a memory buffer)* and *Custom I/O proxies (and writing the file to a memory buffer)*.

In addition to communicating `IOProxy` information via this attribute, it is also allowed (and probably preferred) to directly supply the `IOProxy` information via calls to `ImageInput::open()`, `create()`, and `set_ioproxy()`, `ImageOutput::create()` and `set_ioproxy()`, and `ImageBuf::ImageBuf()`, `reset()`, and `set_write_ioproxy()`.

18.6 Photographs or scanned images

The following metadata items are specific to photos or captured images.

"Make" : string

For captured or scanned image, the make of the camera or scanner.

"Model" : string

For captured or scanned image, the model of the camera or scanner.

"ExposureTime" : float

The exposure time (in seconds) of the captured image.

"FNumber" : float

The f/stop of the camera when it captured the image.

18.7 Thumbnails / postage stamps / preview images

Some image file formats allow for storing a `thumbnail` – a lower-resolution image suitable for an icon or other small preview. These are retrievable separately via `ImageInput::get_thumbnail()`, `ImageBuf::thumbnail()`, or `ImageCache::get_thumbnail()`. In addition, if a thumbnail is available, the `ImageSpec` should also contain the following metadata:

"thumbnail_width" : int

The thumbnail width, in pixels.

"thumbnail_height" : int

The thumbnail height, in pixels.

"thumbnail_nchannels" : int

The number of color channels in the thumbnail image.

18.8 Texture Information

Several standard metadata are very helpful for images that are intended to be used as textures (especially for OpenImageIO's `TextureSystem`).

"textureformat" : string

The kind of texture that this image is intended to be. We suggest the following names:

Plain Texture	Ordinary 2D texture
Volume Texture	3D volumetric texture
Shadow	Ordinary z-depth shadow map
CubeFace Shadow	Cube-face shadow map
Volume Shadow	Volumetric ("deep") shadow map
LatLong Environment	Latitude-longitude (rectangular) environment map
CubeFace Environment	Cube-face environment map

"wrapmodes" : string

Give the intended texture *wrap mode* indicating what happens with texture coordinates outside the $[0...1]$ range. We suggest the following names: `black`, `periodic`, `clamp`, `mirror`. If the wrap mode is different in each direction, they should simply be separated by a comma. For example, `black` means black wrap in both directions, whereas `clamp,periodic` means to clamp in u and be periodic in v .

"fovquot" : float

The cotangent (x/y) of the field of view of the original image (which may not be the same as the aspect ratio of the pixels of the texture, which may have been resized).

"worldtocamera" : matrix44

For shadow maps or rendered images this item (of type `TypeDesc::PT_MATRIX`) is the world-to-camera matrix describing the camera position.

"worldtoscreen" : matrix44

For shadow maps or rendered images this item (of type `TypeDesc::PT_MATRIX`) is the world-to-screen matrix describing the full projection of the 3D view onto a $[-1...1] \times [-1...1]$ 2D domain.

"worldtoNDC" : matrix44

For shadow maps or rendered images this item (of type `TypeDesc::PT_MATRIX`) is the world-to-NDC matrix describing the full projection of the 3D view onto a $[0...1] \times [0...1]$ 2D domain.

"oiio:updirection" : string

For environment maps, indicates which direction is “up” (valid values are y or z), to disambiguate conventions for environment map orientation.

"oiio:sampleborder" : int

If not present or 0 (the default), the conversion from pixel integer coordinates (i, j) to texture coordinates (s, t) follows the usual convention of $s = (i + 0.5)/xres$ and $t = (j + 0.5)/yres$. However, if this attribute is present and nonzero, the first and last row/column of pixels lie exactly at the s or $t = 0$ or 1 boundaries, i.e., $s = i/(xres - 1)$ and $t = j/(yres - 1)$.

"oiio:ConstantColor" : string

If present, is a hint that the texture has the same value in all pixels, and the metadata value is a string containing the channel values as a comma-separated list (no spaces, for example: 0.73,0.9,0.11,1.0).

"oiio:AverageColor" : string

If present, is a hint giving the *average* value of all pixels in the texture, as a string containing a comma-separated list of the channel values (no spaces, for example: 0.73,0.9,0.11,1.0).

"oiio:SHA-1" : string

If present, is a 40-byte SHA-1 hash of the input image (possibly salted with various maketx options) that can serve to quickly compare two separate textures to know if they contain the same pixels. While it's not, technically, 100% guaranteed that no separate textures will match, it's so astronomically unlikely that we discount the possibility (you'd be rendering oovies for centuries before finding a single match).

18.9 Exif metadata

The following Exif metadata tags correspond to items in the “standard” set of metadata.

Exif tag	OpenImageIO metadata convention
ColorSpace	(reflected in “oiio:ColorSpace”)
ExposureTime	ExposureTime
FNumber	FNumber

The other remaining Exif metadata tags all include the **Exif:** prefix to keep it from clashing with other names that may be used for other purposes.

"Exif:ExposureProgram" : int

The exposure program used to set exposure when the picture was taken:

0	unknown
1	manual
2	normal program
3	aperture priority
4	shutter priority
5	Creative program (biased toward depth of field)
6	Action program (biased toward fast shutter speed)
7	Portrait mode (closeup photo with background out of focus)
8	Landscape mode (background in focus)

"Exif:SpectralSensitivity" : string

The camera's spectral sensitivity, using the ASTM conventions.

"Exif:ISOSpeedRatings" : int

The ISO speed and ISO latitude of the camera as specified in ISO 12232.

"Exif:DateTimeOriginal" : string

"Exif:DateTimeDigitized" : string

Date and time that the original image data was generated or captured, and the time/time that the image was stored as digital data. Both are in YYYY:MM:DD HH:MM:SS format.

To clarify the role of these (and also with respect to the standard `DateTime` metadata), consider an analog photograph taken in 1960 (`Exif:DateTimeOriginal`), which was scanned to a digital image in 2010 (`Exif:DateTimeDigitized`), and had color corrections or other alterations performed in 2015 (`DateTime`).

"Exif:CompressedBitsPerPixel" : float

The compression mode used, measured in compressed bits per pixel.

"Exif:ShutterSpeedValue" : float

Shutter speed, in APEX units: $-\log_2(exposuretime)$

"Exif:ApertureValue" : float

Aperture, in APEX units: $2\log_2(fnumber)$

"Exif:BrightnessValue" : float

Brightness value, assumed to be in the range of $-99.99 - 99.99$.

"Exif:ExposureBiasValue" : float

Exposure bias, assumed to be in the range of $-99.99 - 99.99$.

"Exif:MaxApertureValue" : float

Smallest F number of the lens, in APEX units: $2\log_2(fnumber)$

"Exif:SubjectDistance" : float

Distance to the subject, in meters.

"Exif:MeteringMode" : int

The metering mode:

0	unknown
1	average
2	center-weighted average
3	spot
4	multi-spot
5	pattern
6	partial
255	other

"Exif:LightSource" : int

The kind of light source:

0	unknown
1	daylight
2	tungsten (incandescent light)
4	flash
9	fine weather
10	cloudy weather
11	shade
12	daylight fluorescent (D 5700-7100K)
13	day white fluorescent (N 4600-5400K)
14	cool white fluorescent (W 3900 - 4500K)
15	white fluorescent (WW 3200 - 3700K)
17	standard light A
18	standard light B
19	standard light C
20	D55
21	D65
22	D75
23	D50
24	ISO studio tungsten
255	other light source

"Exif:Flash" int}

A sum of:

1	if the flash fired
0	no strobe return detection function
4	strobe return light was not detected
6	strobe return light was detected
8	compulsory flash firing
16	compulsory flash suppression
24	auto-flash mode
32	no flash function (0 if flash function present)
64	red-eye reduction supported (0 if no red-eye reduction mode)

"Exif:FocalLength" : float

Actual focal length of the lens, in mm.

"Exif:SecurityClassification" : string

Security classification of the image: C = confidential, R = restricted, S = secret, T = top secret, U = unclassified.

"Exif:ImageHistory" : string

Image history.

"Exif:SubsecTime" : string

Fractions of a second to augment the "DateTime" (expressed as text of the digits to the right of the decimal).

"Exif:SubsecTimeOriginal" : string

Fractions of a second to augment the Exif:DateTimeOriginal (expressed as text of the digits to the right of the decimal).

"Exif:SubsecTimeDigitized" : string

Fractions of a second to augment the Exif:DateTimeDigital (expressed as text of the digits to the right of the decimal).

"Exif:PixelXDimension" : int

"Exif:PixelYDimension" : int

The x and y dimensions of the valid pixel area.

"Exif:FlashEnergy" : float

Strobe energy when the image was captures, measured in Beam Candle Power Seconds (BCPS).

"Exif:FocalPlaneXResolution" : float

"Exif:FocalPlaneYResolution" : float

"Exif:FocalPlaneResolutionUnit" : int

The number of pixels in the x and y dimension, per resolution unit. The codes for resolution units are:

1	none
2	inches
3	cm
4	mm
5	μm

"Exif:ExposureIndex" : float

The exposure index selected on the camera.

"Exif:SensingMethod" : int

The image sensor type on the camra:

1	undefined
2	one-chip color area sensor
3	two-chip color area sensor
4	three-chip color area sensor
5	color sequential area sensor
7	trilinear sensor
8	color trilinear sensor

"Exif:FileSource" : int

The source type of the scanned image, if known:

1	film scanner
2	reflection print scanner
3	digital camera

"Exif:SceneType" : int

Set to 1, if a directly-photographed image, otherwise it should not be present.

"Exif:CustomRendered" : int

Set to 0 for a normal process, 1 if some custom processing has been performed on the image data.

"Exif:ExposureMode" : int

The exposure mode:

0	auto
1	manual
2	auto-bracket

"Exif:WhiteBalance" : int

Set to 0 for auto white balance, 1 for manual white balance.

"Exif:DigitalZoomRatio" : float

The digital zoom ratio used when the image was shot.

"Exif:FocalLengthIn35mmFilm" : int

The equivalent focal length of a 35mm camera, in mm.

"Exif:SceneCaptureType" : int

The type of scene that was shot:

0	standard
1	landscape
2	portrait
3	night scene

"Exif:GainControl" : float

The degree of overall gain adjustment:

0	none
1	low gain up
2	high gain up
3	low gain down
4	high gain down

"Exif:Contrast" : int

The direction of contrast processing applied by the camera:

0	normal
1	soft
2	hard

"Exif:Saturation" : int

The direction of saturation processing applied by the camera:

0	normal
1	low saturation
2	high saturation

"Exif:Sharpness" : int

The direction of sharpness processing applied by the camera:

0	normal
1	soft
2	hard

"Exif:SubjectDistanceRange" : int

The distance to the subject:

0	unknown
1	macro
2	close
3	distant

"Exif:ImageUniqueID" : string

A unique identifier for the image, as 16 ASCII hexadecimal digits representing a 128-bit number.

18.10 GPS Exif metadata

The following GPS-related Exif metadata tags correspond to items in the “standard” set of metadata.

"GPS:LatitudeRef" : string

Whether the GPS:Latitude tag refers to north or south: N or S.

"GPS:Latitude" : float[3]

The degrees, minutes, and seconds of latitude (see also GPS:LatitudeRef).

"GPS:LongitudeRef" : string

Whether the GPS:Longitude tag refers to east or west: E or a W.

"GPS:Longitude" : float[3]

The degrees, minutes, and seconds of longitude (see also GPS:LongitudeRef).

"GPS:AltitudeRef" : string

A value of 0 indicates that the altitude is above sea level, 1 indicates below sea level.

"GPS:Altitude" : float

Absolute value of the altitude, in meters, relative to sea level (see GPS:AltitudeRef for whether it's above or below sea level).

"GPS:TimeStamp" : float[3]

Gives the hours, minutes, and seconds, in UTC.

"GPS:Satellites" : string

Information about what satellites were visible.

"GPS:Status" : string

A indicates a measurement in progress, V indicates measurement interoperability.

"GPS:MeasureMode" : string

2 indicates a 2D measurement, 3 indicates a 3D measurement.

"GPS:DOP" : float

Data degree of precision.

"GPS:SpeedRef" : string

Indicates the units of the related GPS:Speed tag: K for km/h, M for miles/h, N for knots.

"GPS:Speed" : float

Speed of the GPS receiver (see GPS:SpeedRef for the units).

"GPS:TrackRef" : string

Describes the meaning of the GPS:Track field: T for true direction, M for magnetic direction.

"GPS:Track" : float

Direction of the GPS receiver movement (from 0–359.99). The related GPS:TrackRef indicate whether it's true or magnetic.

"GPS:ImgDirectionRef" : string

Describes the meaning of the GPS:ImgDirection field: T for true direction, M for magnetic direction.

"GPS:ImgDirection" : float

Direction of the image when captured (from 0–359.99). The related GPS:ImgDirectionRef indicate whether it's true or magnetic.

"GPS:MapDatum" : string

The geodetic survey data used by the GPS receiver.

"GPS:DestLatitudeRef" : string

Whether the GPS:DestLatitude tag refers to north or south: N or S.

"GPS:DestLatitude" : float[3]

The degrees, minutes, and seconds of latitude of the destination (see also GPS:DestLatitudeRef).

"GPS:DestLongitudeRef" : string

Whether the GPS:DestLongitude tag refers to east or west: E or W.

"GPS:DestLongitude" : float[3]

The degrees, minutes, and seconds of longitude of the destination (see also GPS:DestLongitudeRef).

"GPS:DestBearingRef" : string

Describes the meaning of the GPS:DestBearing field: T for true direction, M for magnetic direction.

"GPS:DestBearing" : float

Bearing to the destination point (from 0–359.99). The related GPS:DestBearingRef indicate whether it's true or magnetic.

"GPS:DestDistanceRef" : string

Indicates the units of the related GPS:DestDistance tag: K for km, M for miles, N for knots.

"GPS:DestDistance" : float

Distance to the destination (see GPS:DestDistanceRef for the units).

"GPS:ProcessingMethod" : string

Processing method information.

"GPS:AreaInformation" : string

Name of the GPS area.

"GPS:DateStamp" : string

Date according to the GPS device, in format YYYY:MM:DD.

"GPS:Differential" : int

If 1, indicates that differential correction was applied.

"GPS:HPositioningError" : float

Positioning error.

18.11 IPTC metadata

The IPTC (International Press Telecommunications Council) publishes conventions for storing image metadata, and this standard is growing in popularity and is commonly used in photo-browsing programs to record captions and keywords.

The following IPTC metadata items correspond exactly to metadata in the OpenImageIO conventions, so it is recommended that you use the standards and that plugins supporting IPTC metadata respond likewise:

IPTC tag	OpenImageIO metadata convention
Caption	"ImageDescription"
Keyword	IPTC keywords should be concatenated, separated by semicolons (;), and stored as the Keywords attribute.
Exposure-Time	ExposureTime
Copyright-Notice	Copyright
Creator	Artist

The remainder of IPTC metadata fields should use the following names, prefixed with IPTC: to avoid conflicts with other plugins or standards.

"IPTC:ObjectTypeReference" : string

Object type reference.

"IPTC:ObjectAttributeReference" : string

Object attribute reference.

"IPTC:ObjectName" : string

The name of the object in the picture.

"IPTC:EditStatus" : string

Edit status.

"IPTC:SubjectReference" : string

Subject reference.

"IPTC:Category" : string

Category.

"IPTC:ContentLocationCode" : string

Code for content location.

"IPTC:ContentLocationName" : string

Name of content location.

"IPTC:ReleaseDate" : string

"IPTC:ReleaseTime" : string

Release date and time.

"IPTC:ExpirationDate" : string

"IPTC:ExpirationTime" : string

Expiration date and time.

"IPTC:Instructions" : string

Special instructions for handling the image.

"IPTC:ReferenceService" : string

"IPTC:ReferenceDate" : string

"IPTC:ReferenceNumber" : string

Reference date, service, and number.

"IPTC:DateCreated" : string

"IPTC:TimeCreated" : string

Date and time that the image was created.

"IPTC:DigitalCreationDate" : string

"IPTC:DigitalCreationTime" : string

Date and time that the image was digitized.

"IPTC:ProgramVersion" : string

The version number of the creation software.

"IPTC:AuthorsPosition" : string

The job title or position of the creator of the image.

"IPTC:City" : string

"IPTC:Sublocation" : string

"IPTC:State" : string

"IPTC:Country" : string

"IPTC:CountryCode" : string

The city, sublocation within the city, state, country, and country code of the location of the image.

"IPTC:Headline" : string

Any headline that is meant to accompany the image.

"IPTC:Provider" : string

The provider of the image, or credit line.

"IPTC:Source" : string

The source of the image.

"IPTC:Contact" : string

The contact information for the image (possibly including name, address, email, etc.).

"IPTC:CaptionWriter" : string

The name of the person who wrote the caption or description of the image.

"IPTC:JobID" : string

"IPTC:MasterDocumentID" : string

"IPTC:ShortDocumentID" : string

"IPTC:UniqueDocumentID" : string

"IPTC:OwnerID" : string

Various identification tags.

"IPTC:Prefs" : string

"IPTC:ClassifyState" : string

"IPTC:SimilarityIndex" : string

Who knows what the heck these are?

"IPTC:DocumentNotes" : string

Notes about the image or document.

"IPTC:DocumentHistory" : string

The history of the image or document.

18.12 SMPTE metadata

"smpte:TimeCode" : int[2]

SMPTE time code, encoded as an array of 2 32-bit integers (as a `TypeDesc`, it will be tagged with vecsemantics TIMECODE).

"smpte:KeyCode" : int[7]

SMPTE key code, encoded as an array of 7 32-bit integers (as a `TypeDesc`, it will be tagged with vecsemantics KEYCODE).

18.13 Extension conventions

To avoid conflicts with other plugins, or with any additional standard metadata names that may be added in future versions of OpenImageIO, it is strongly advised that writers of new plugins should prefix their metadata with the name of the format, much like the `"Exif:"` and `"IPTC:"` metadata.

GLOSSARY

Channel

One of several data values present in each pixel. Examples include red, green, blue, alpha, etc. The data in one channel of a pixel may be represented by a single number, whereas the pixel as a whole requires one number for each channel.

Client

A client (as in “client application”) is a program or library that uses OpenImageIO or any of its constituent libraries.

Data format

The representation used to store a piece of data. Examples include 8-bit unsigned integers, 32-bit floating-point numbers, etc.

Image File Format

The specification and data layout of an image on disk. For example, TIFF, JPEG/JFIF, OpenEXR, etc.

Image Format Plugin

A DSO/DLL that implements the ImageInput and ImageOutput classes for a particular image file format.

Format Plugin

See *image format plugin*.

Metadata

Data about data. As used in OpenImageIO, this means Information about an image, beyond describing the values of the pixels themselves. Examples include the name of the artist that created the image, the date that an image was scanned, the camera settings used when a photograph was taken, etc.

Multi-part image / multi-part file

This is what OpenEXR calls a file containing multiple subimages.

Native data format

The *data format* used in the disk file representing an image. Note that with OpenImageIO, this may be different than the data format used by an application to store the image in the computer’s RAM.

Pixel

One pixel element of an image, consisting of one number describing each *channel* of data at a particular location in an image.

Plugin

See *image format plugin*.

Scanline

A single horizontal row of pixels of an image. See also *tile*.

Scanline Image

An image whose data layout on disk is organized by breaking the image up into horizontal scanlines, typically with the ability to read or write an entire scanline at once. See also *tiled image*.

Subimage

Some image file formats allow the storage of multiple images in each file. These are called *subimages* in OpenImageIO. Note that in OpenEXR, these are called multi-part files.

Thumbnail

A small, lower-resolution preview image that is stored in an image file, in addition to the main image that the file represents. Not all image file formats support thumbnails.

Tile

A rectangular region of pixels of an image. A rectangular tile is more spatially coherent than a scanline that stretches across the entire image — that is, a pixel’s neighbors are most likely in the same tile, whereas a pixel in a scanline image will typically have most of its immediate neighbors on different scanlines (requiring additional scanline reads in order to access them).

Tiled Image

An image whose data layout on disk is organized by breaking the image up into rectangular regions of pixels called tiles. All the pixels in a tile can be read or written at once, and individual tiles may be read or written separately from other tiles.

Volume Image

A 3-D set of pixels that has not only horizontal and vertical dimensions, but also a “depth” dimension.
